Upon discharge, or, in the case of a member of the Reserve or Territorial Forces, upon the demobilisation or disembodiment of these forces, the insured person will again become entitled to medical benefit under the National Insurance Acts (unless otherwise disentitled); and he will then be entitled to make a selection of the method by which he desires to obtain treatment as though he had newly entered into insurance. In such cases where an insured person on return from service takes up a new residence, the arrangements which are already in existence for "removals" and "temporary residents" will apply.

THE STATUS OF MEDICAL PARTNERSHIPS UNDER THE INSURANCE ACT.

At a recent meeting of the Panel Committee for the County of London the Panel Service Subcommittee submitted the opinion of counsel (Mr. F. Gore Browne, K.C.) upon questions laid before him as to the legal position of the members of a firm or partnership of medical practitioners under the Insurance Act. In substance Mr. Gore Browne advised that a firm or partnership is not a separate entity at law, that the Act contemplates arrangements with individual practitioners only, and that any agreement purporting to deal with a firm as such would be irregular. He was of opinion that "the arrangements with the respective members of a firm might be embodied in a single agreement, but the right of the insured under Section 15 (2) (*c*) to select a practitioner would give him the right to select which partner he chose, and the agreement would have to contain a provision to that effect—the agreement would not be a joint agreement in this case, but a number of separate agreements included in one document." Further, a committee could not be called upon to agree with a firm as such or with its respective members in one document, and can insist upon arrangements already made being so far modified as to make them comply with the Act. He also said that the Acts and Regulations do not deal with partnership cases, so that changes in partnership are not matters of which notice to insured persons treated by members of a partnership can be insisted on by a committee. It need hardly be said that Mr. Gore Browne is a member of the Bar whose advice carries all the weight attachable to "counsel's opinion."

EXCESSIVE COST OF PRESCRIPTIONS.

The Pharmacy Committee of the London Panel Committee has had before it 40 cases in which representations have been made by the Pharmaceutical Committee alleging excess in the cost of drugs and appliances prescribed. In five cases no investigation was made owing to the medical practitioners affected being absent from their practices on military duty. In 17 cases it was found that there was excess, in 9 that there was not, and in the remaining 9 that the period under review (April 12th to 30th, 1914) was not sufficiently extensive to enable the subcommittee to decide whether the cost of the drugs and appliances ordered by the practitioner was or was not in excess of what was reasonably necessary for adequate treatment of his patients.

INSURANCE WORK WHEN THE WAR IS OVER.

At a meeting of the West Sussex Insurance Committee the Rev. W. D. Yoward, chairman, called attention to the changed conditions with regard to the working of the Insurance Act likely to prevail when the war is over, and a resolution was carried inviting the National Association of Insurance Committees to take steps to prepare beforehand for what might be expected. It was suggested that as a result of the war thousands of men now serving or about to serve are likely to return and again become insured persons with greatly impaired health. This would mean that a much larger number of persons would probably require the benefits of the Act during a period following demobilisation than would have been the case upon the normal actuarial basis, if there had been no war. The strain in such an event would be felt by the committees and approved societies, and among those who would be affected would be the medical practitioners and the druggists. The question is one of importance, and will no doubt claim and receive the attention of the Government when it arises, but discussion preceding the necessity for immediate action will do no harm. In the discussion on the occasion referred to it was pointed out that a proportion of the incapacity due to the war would necessarily be met as such by the Government independently of insurance.

UNIVERSITY OF LONDON.—The Paul Philip Reitlinger Prize, offered this year for an essay embodying the result of research work on a medical subject, has been awarded to Alfred Hope Gosse, M.A., M.B. Camb., M.R.C.P., London Hospital Medical College, for an essay on "The Heart in Acute Rheumatism with Special Reference to Graphic Methods of Investigation." The prize, this year of the value of £40, was founded with funds given to the University by Mr. Albert Reitlinger in memory of his son, a student of St. George's Hospital Medical School, who died on Dec. 3rd, 1911. Next year the prize will be offered for the best essay on "The Economic Condition of the People of England in 1815 in Comparison with the Present Day."

Obituary.

WALTER JENNINGS MILLES, M.D. BRUX., F.R.C.S. ENG.

ALL those who knew Dr. Jennings Milles will have seen the notice of his sudden death on Oct. 22nd with the sincerest regret. He was born at St. Margaret's, Collier-street, Yalding, Kent, on March 21st, 1854, and was the second surviving son of the late Rev. T. Milles, vicar of that parish for 30 years. He was educated at Tonbridge School, where he not only worked well but distinguished himself as an athlete, becoming captain of the first XV. He subsequently studied medicine at King's College, London, and qualified as M.R.C.S. Eng. in 1877 and L.R.C.P. Lond. in 1879. He took the diploma of F.R.C.S. in 1880, and on one of his subsequent visits to Europe in 1890 took the M.D. degree of Brussels.

After he qualified Dr. Milles was appointed house surgeon to the late Mr. John Wood at King's College Hospital, and subsequently became surgical registrar. His tastes led him to pay special attention to ophthalmic surgery, and he subsequently became house surgeon to the Ophthalmic Hospital, Moorfields. He then commenced practice in London as an ophthalmic surgeon, and had he remained in London there can be no doubt that he would have become one of our leading ophthalmic surgeons.

In 1884, however, he was asked to join the firm of Henderson and Macleod in Shanghai, then the leading medical firm in Shanghai, if not also in the East, and after much consideration he decided to accept the offer, and sailed for China on June 18th, 1884. He practised there for 26 years, retiring on account of ill-health in 1910.

While he was in London he did a good deal of work on the pathology of the eye and also became much interested in bacteriology. In 1878 he commenced a research in collaboration with Mr. A. S. Underwood on the bacteriology of the teeth, and their work demonstrated the important part that bacteria play in caries of the teeth. Their results were brought before the International Medical Congress in 1881, and will be found in the Transactions of that Congress. In China he quickly became immersed in the work of a large general practice, especially in surgical and ophthalmic work, and his opinion on the latter subject was especially sought after not only by the Europeans but by the Chinese. He was surgeon-major in the Shanghai Volunteers, and received the China medal after the Boxer riots in 1900. He also received the Order of Anam after the Russo-Japanese war.

Dr. Milles was a man of most kindly and sympathetic disposition; no trouble was too great to help a friend or patient, and throughout his life he was a great favourite with all with whom he came in contact. Enthusiastic in his work, gentle in his manners, sound in his judgment, and without any self-conceit, he was one of the best types of medical men, and his loss will be much felt among his large circle of acquaintances.

He leaves a widow and three children to mourn their loss.

HUGH RICHARD KER, F.R.C.S. EDIN., L.R.C.P. EDIN., M.R.C.S. ENG.

THE death of Mr. H. R. Ker, which took place at his residence, "Tintern," Balham Hill, where till recently he was in practice, will leave a gap in his district.

He was one of the old school of practitioners who began their professional careers under the apprenticeship system, was educated later at Guy's Hospital and qualified in 1871 as M.R.C.S. Eng., obtaining the Fellowship of the Royal College of Surgeons of Edinburgh in 1880. For a time he acted as clinical assistant at the Evelina Hospital for Sick Children. He was a Fellow of the Royal Society of Medicine and the Medical Society of London, a former Fellow of the Obstetrical Society, and ex-President of the South-West London Medical Society and of the Midland Medical Society. In the earlier years of his professional life he practised in the Black Country, where he gained reputation as a surgeon and an obstetrician. After a successful career in the Midlands he came to London and settled in partnership at Balham about 25 years ago. Here he rapidly came to the front and enjoyed a large practice. His varied experience stood him in good stead, and he was always ready to take charge of any case which fell to his care with sound judgment. He dealt with medicine, surgery, obstetrics, and gynæcology with the confidence and success of the old school from which he came. In Balham he was well known and much liked by his patients, to whom he was a kind and skilled adviser, never sparing himself trouble, and always ready to render assistance at any hour. He will be much missed among his friends and patients.

JOHN McILROY, M.D. R.U.I., J.P.

WE regret to announce the death of a well-known Belfast practitioner, Dr. John McIlroy, which occurred on Nov. 20th at his residence, York-street, in that city. Dr. McIlroy, who was in his sixty-sixth year, had been in failing health for the past six months, but was able to attend to his practice until four weeks ago. A county Londonderry man, born in Kilrea, Dr. McIlroy went to Belfast in the "seventies" of the past century, and studied at Queen's College. In 1876 he obtained the L.F.P.S. Glasg., in 1882 the L.R.C.P. Irel., and in 1883 graduated M.D. of the Royal University, taking the B.A.O. ten years later. Settling down in the north end of the city of Belfast, Dr. McIlroy rapidly acquired by his ability, care, and attention a large practice. He was greatly liked and trusted by his patients. He was medical referee for the Prudential Assurance Company, and surgeon to the Midland Railway Company and to the Clyde Shipping Company. He was a justice of the peace for the city of Belfast and a member of the city council, having in 1909 been elected a councillor for one of the wards, and he held his seat until his decease.

Professor G. Sims Woodhead, M.D., will open a discussion on Preventive Inoculation at the Royal Sanitary Institute, 90, Buckingham Palace-road, on Tuesday next, Dec. 8th. The chair will be taken at 7.30 P.M. by Sir Shirley Murphy.

THE WAR.

THE DISTINGUISHED SERVICE ORDER.

IT was announced by the War Office on Dec. 1st that His Majesty the King (who was then with his troops at the front) had approved the appointment of 58 officers to be Companions of the Distinguished Service Order, in recognition of their services with the Expeditionary Force. The list includes the names of three officers of the Royal Army Medical Corps, whose services entitling them to this distinction are officially described in the following terms:—

Captain James Stuart Dunne:

> During German attack on night of Oct. 31st, near Messines, he established a dressing station just behind the trenches, and was the means of saving many lives, he himself going several times into the trenches to attend to wounded men who could not be moved.

Captain Sidney John Steward:

> Went with party of stretcher-bearers across ground swept by rifle and shell fire to Langemark village and removed 11 wounded men.

Captain Patrick Sampson:

> Has shown frequent and conspicuous gallantry throughout the campaign, especially on Oct. 21st and 22nd, attending wounded men under very heavy shell fire.

THE CASUALTY LIST.

This week we have to record the death of the three medical officers serving in H.M.S. *Bulwark*, who are officially stated by the Admiralty to have been on board the ill-fated battleship when she was blown up on Nov. 26th at the mouth of the Medway. The names are: Fleet-Surgeon Percival Kent Nix, R.N., Surgeon William Miller, R.N., and Surgeon Robert Traill Brotchie, R.N.V.R.

The following casualties among officers of the Royal Army Medical Corps and the Indian Medical Service serving with the Expeditionary Forces have been reported since our last issue:—

Died of wounds: Major Edwin Bedford Steel, R.A.M.C.

Missing: Captain H. G. Robertson, R.A.M.C.

Captain A. M. Rose, R.A.M.C., previously reported wounded and missing, and Lieutenant H. G. Winter, R.A.M.C., and Lieutenant J. L. Jackson, R.A.M.C., previously reported missing, are now unofficially reported prisoners of war.

Lieutenant N. M. Mehta, I.M.S., previously reported missing, has now rejoined the British force operating in East Africa.

ADMISSIONS TO THE MILITARY HOSPITALS.

The relative proportion of sick and wounded admitted to the Military base hospitals will probably vary considerably from time to time. This is shown by the experience at the Third London General Hospital. During the heavy fighting in Northern France and in Belgium a large number of wounded were admitted and very few sick, so much so that the wards which were intended for purely medical cases were occupied to a large extent by surgical cases, and the services of the physicians were used in attendance on those men who were lightly wounded. Since the lull in the fighting and the onset of cold and damp weather a larger proportion of sick have been sent from Belgium, and the medical wards have again reverted to the sole care of the physicians. The cases for the most part are of a slight nature, subacute rheumatism preponderates, with a certain number of men suffering from slight bronchial catarrh.

FIELD SURGERY AND TRENCH HYGIENE.

We would particularly draw the attention of our readers to the full report which we print this week in our Parliamentary Intelligence of the contribution by the Under Secretary of State for War, Mr. Tennant, to a discussion in the House of Commons on the treatment of the wounded in the war, and to his concluding remarks on the efforts which have been made to ensure hygienic conditions for our brave soldiers in the trenches. With regard to the arrangements for the treatment of wounded men at the front Mr. Tennant pointed out that while everything possible is being done to secure that effective treatment is carried out with the least possible delay, the actual moment at which the wounded can be removed from the firing line must be largely determined by military exigencies. Thus the question of the promptness or otherwise of surgical treatment is really more a military than a surgical question. The public generally will be relieved to learn, on the positive assurance of the Under Secretary for War, that the Royal Army Medical Corps possess at the present time ample numbers of officers and men, and that there is a sufficient supply of trained nurses at the clearing stations to which our wounded are taken from the first-aid posts on their way to the base.

The statement, repeated in the most explicit terms, that there is an ample supply both of personnel and of matériel for the medical needs of the Expeditionary Force will bring relief to a great many minds. Mr. Tennant spoke in the warmest terms of the skill and devotion of all ranks of the Royal Army Medical Corps, and acknowledged the value of the services of those distinguished members of our profession who have left their civilian duties in order to advise and assist the medical military authorities at the front. As our readers will have judged from the interesting report on Gas Gangrene by Sir Anthony Bowlby and Dr. J. Sydney Rowlands which we published last week, bacteriological investigations made on the spot by expert workers are already yielding useful fruit, and will no doubt contribute more and more in the future to the prevention and early treatment of wound infections and to the maintenance of the general health of our troops. It is very satisfactory to learn in this connexion that the Royal Army Medical Corps is working in close touch with such centres of scientific investigation as the Lister Institute and the Research Committee set up under the National Insurance Act. The fact that these two institutions are likely to remain separate and distinct, at least for some time to come, will not in any way impair the services which each can render to the public and to those who are heroically fighting in its defence.

With regard to hospital trains on the other side of the Channel and to transport of the wounded generally, it seems fairly clear that conditions have improved and are improving. As we pointed out two or three months ago, when rumours were rife of a medical breakdown at the front, the circumstances of a prolonged and rapid retirement of an army such as occurred in the retreat from Mons rendered field surgery, except of the roughest character, a matter of most extreme difficulty. At such a time the best-laid plans break down, and in the face of military emergencies medical organisation of a field force for the moment falls to pieces. When we look back with our present knowledge upon the events in France of the last days of August we realise the almost impossible task of the Royal Army Medical Corps, and are thankful that things were not a great deal worse. Now that the Western military situation has settled down more or less into an affair of fixed trenches, the arrangements for early and efficient treatment of the wounded have steadily improved.

Now while the surgical and administrative arrangements for dealing with those who have already fallen in battle appeal more directly to the mind and the imagination, we must not forget the enormous importance of sanitation. As winter advances the problems of trench hygiene become more difficult and more pressing, but we are glad to learn from Mr. Tennant and through private sources that these problems are being tackled with the utmost skill and energy. The evidence up to the present is that the health of our troops in the field is being maintained in a satisfactory manner, and that foresight is being exercised in every direction to minimise future risks. We are confident that the Sanitary Committee which has been sent out to the front to prepare the ground for the work of divisional sanitary companies and to advise the military authorities generally, will prove of the greatest value to our forces. The reason for not publishing in any detail the steps taken to preserve the health of British soldiers at the front will appeal at once to our readers. We do not wish to make a present to the enemy of our own carefully thought out and practically tested methods of trench sanitation. The fact that there have so far been very few cases of enteric fever in circumstances which are wholly favourable for the spread of this disease bears testimony to the excellent medical arrangements in the army. The very large proportion of men who have undergone antityphoid inoculation before proceeding to France and Belgium no doubt accounts to a considerable degree for our freedom from this curse of armies, but it would be too much to expect that this measure alone without the most vigilant attention to sanitation would be enough. The action of the joint committee of the British Red Cross Society and the Order of St. John in making this week an immediate advance of £10,000 for the assistance of Belgian soldiers at Calais suffering from enteric fever indicates that the Belgian army in the field is now threatened with a typhoid epidemic. How serious the situation may be we are not in a position to say at present, but we feel confident that even if such an epidemic spreads among the Allies who are operating in the neighbourhood of the British army the measures which are being taken to protect our own troops will not prove in vain.

The Care of the Belgian Wounded.

Our Special Sanitary Commissioner gives below an account of the machinery, official and private, which has been employed in the succour of the Belgian wounded in this country.

British Help for the Belgian Wounded.

It will be remembered that the first organised attempt to assist the Belgian refugees, was done entirely by private enterprise. Only after close upon 8000 refugees had been provided for and some hundred thousand letters received, did the Government come to the rescue and convert the War Refugees' Committee into a new official department under the Local Government Board. While the women, children, the civilian population, flying from the devastation of their homes and country had thus been provided for, we had not yet realised that, as nearly the whole of Belgium was overrun by the invaders, there could remain no efficient provision for the wounded Belgian soldiers. Not only was the Belgian military medical service shattered and scattered, but, as the Germans occupied all the important towns of the country, they were in possession of all the large hospitals. Antwerp and Ostend alone remained, and it was not likely that the Belgians would retain their hold on these towns for long. Even if the Belgians continued to hold Antwerp, the most they could do in their overcrowded hospitals was to attend to severe cases. To make room for these the convalescent should be sent away at the earliest date. It then occurred to a group of men on the spot, Dr. G. B. Clark being prominent among these, that we should receive in England the convalescent, and, if necessary, the wounded Belgian soldiers in the same manner as we were already receiving the refugees—namely, as guests of the nation. Even if the wounded could still be treated at Antwerp and Ostend, their homes had been destroyed, and they had nowhere to go when convalescent.

Flight of the Wounded from Antwerp.

In the hope that action might be taken in England the British Red Cross was approached. The necessity of such action was readily acknowledged, but the mission of the British Red Cross was to attend to the British wounded, and they hardly felt justified in interfering with Belgian affairs. If, however, anyone else could do so they would gladly help and subscribe £1000 towards the expenses. Further, if a committee was formed for that purpose Sir Rowland Bailey, C.B., of the Red Cross Society, consented to be a member. In this manner the Wounded Allies Relief Committee came into existence. The *Daily Chronicle* and the *Observer* each gave £1000 out of the money already collected for the Belgian refugees. Thus there were £3000 to start with, and, of course, larger sums have come in since. A strong committee was formed, including some distinguished Belgians, such as Senator La Fontaine, the Bishop of Birmingham, Lord Onslow, Lord George Hamilton, and Sir William Collins. Count de Lalaing, the Belgian Minister, frequently attends the committee meetings to advise and assist on behalf of the Belgian Government. Mr. R. C. Hawkin is acting as honorary secretary, and the Hon. Mrs. F. Guest and Mr. T. O. Roberts as honorary treasurers. After making some preparations in England for the reception and care of Belgian wounded, Dr. Clark and his son, Dr. W. Clark, went to Antwerp to bring over to England a first batch of 50 convalescent wounded. By that time, however, the town was in such danger of being captured by the Germans that most of the convalescent had already been removed. It was thereupon arranged to take away 50 soldiers from the military hospital who were not quite convalescent. But events marched too rapidly even for this modest plan to be realised. On Saturday, Oct. 3rd, the quay at Antwerp was in a state of terrible confusion, and the agent of the Great Eastern Railway Company had received orders to allow French and British subjects only on board. The Belgians, being in their own country, were supposed to be able to take care of themselves—a somewhat harsh conclusion if we remember how very little of that country remained to them. Further, it was announced that the boat might start at any moment. Therefore it was no longer possible to take the 50 Belgian soldiers over. Fortunately the evacuation of the wounded from Antwerp had been pressed forward for more than a week previously, while the road by land along the coast was still open.

Wholesale Rescue Work at Ostend.

The members of the committee then secured premises for a hospital at Ramsgate, and sent Dr. W. Clark and Dr. W. A. Brend to Ostend, where they arrived just before the fall of Antwerp. Here they were met by Surgeon-General Meleiss and Inspector-General Derache, of the Belgian army, who were the more perplexed over the presence at Ostend of 10,000 wounded, as 3000 additional wounded were announced to arrive on the morrow. The state of affairs at that time was appalling beyond words. Some 1500 wounded were crowded into the Palace Hotel, though there were but 350 beds in the place. Every available space and even railway sidings were taken up by the wounded. There were very few surgeons present or trained nurses and hardly any medical stores. Some Sisters of Mercy, very devoted but very ignorant, wanted to remove bandages to show the severity of the wounds, hoping to excite commiseration but ignoring the danger of septic poisoning. The supply of antiseptics was exhausted. This terrible state of affairs was met by Mr. Hawkin, by prompt communication with the War Office, the Admiralty, and the Red Cross Society. The committee also sent telegrams to the mayors of a number of large towns asking if they would undertake to receive batches of 50 wounded Belgian soldiers and see that they were properly treated in the local hospitals. Most of the mayors readily assented, and the Admiralty, on its side, promised to send five transport ships in 36 hours. The next day members of the Wounded Allies Relief Committee were back in Ostend with the good news that help was coming; but there was some delay, for the *Copenhagen* and the *Munich*, of the Great Eastern Railway Company, did not arrive until the Belgian army, in view of the rapid advance of the Germans, had already evacuated Ostend. There was the greatest difficulty to find ambulances or stretcher-bearers to bring the wounded to the boat. At length the *Copenhagen*, with 480 Belgian and 68 British wounded, sailed. The *Munich* was at once berthed in her place, and was also quickly filled up with victims of the war. These boats went to Folkestone, where the naval and military authorities helped to disembark their melancholy freight of passengers. One ambulance train was then and there filled up with 450 wounded and sent off to the north of England under the care of Dr. W. Clark. During Oct. 13th, 14th, and 15th the Admiralty transport ships were busily engaged bringing to Dover the wounded from Ostend. Altogether, from Oct. 12th to 15th some 12,000 wounded were conveyed to these shores.

Private Help Harmonising with State Help.

That all this should have been done between Oct. 10th and Oct. 15th conveys the useful teaching that war leaves no time for preparations, and disaster must result if these are not taken in hand well in advance. The Wounded Allies Relief Committee had made some preparations and were able to place 1500 patients upon landing. The greater number, however, had to be taken over by the military and naval authorities and by the Voluntary Aid Detachments of our Territorial Army. But the latter also were not all ready for this work. In several instances the Wounded Allies Relief Committee gave them instruments, furniture, and various necessary things to convert into suitable hospitals the halls or other premises they hastily secured. But altogether very efficient aid has been given to the wounded of the heroic Belgian army. At the present moment some 18,000 wounded Belgians are actually under treatment in England. But would this help have come in time and proved as efficient had it not been for the initiative, the enterprise, and the early warning given by private individuals? On the other hand, both the War Office and the Admiralty are to be congratulated for having followed the example of the Local Government Board, by fully availing themselves of the intelligent services organised by private enterprise and paid for by voluntary contributions. This welding together of the official with the unofficial is a delicate matter, as anyone with the slightest experience will not fail to acknowledge. But it has to be done, for this is a time when all the vital forces of the nation must be utilised.

AN "OPEN LETTER" FROM HAMBURG.

The following is a translation of an "open letter to the medical profession of England" which has been received *viâ* Rotterdam by some medical men in London holding official posts:—

It has been established beyond all doubt, not by rumours, but by authentic depositions, that numerous defenceless and blameless Germans have for months been confined in so-called concentration camps in various places throughout England. On the Newbury racecourse, for instance, there are some 1500 Germans huddled together in such a fashion that six and eight and recently even 12 individuals live and sleep in a three metre wide draughty stall, which in ordinary times serves for a single horse. The sole furniture of this horse-stall, now used as a shelter for human beings, consists of some straw and two coverlets for bedclothes. There is neither table nor seat; opportunities for washing are got from a pump in the court. The prisoners have to cook their own food on open asphalt floors. The menu consists of tea, with one piece of white bread and margarine, morning and evening, and one piece of meat and two potatoes in the middle of the day. Owing to delay in supplying fuel, however, the midday meal is often delayed to 6 o'clock, and, still more often, the meat runs short, or both meat and potatoes are not edible, so that some of the prisoners refuse them and are forced to go hungry. To add to their cup of misery, want of ordinary hygiene has recently resulted in their being unable to keep themselves and their abodes free from vermin. Complaints are useless; in fact, when repeated they cause stricter measures to be taken, such as confinement in small tents erected on clayey meadows and surrounded by water ditches. No attempt is made to discriminate between different degrees of social standing and education. Thus, since Sept. 11th six physicians have been interned at Newbury, a number lately increased to 13. Requests in writing from these medical men, who are willing to interest themselves in the work of English hospitals, have not received any attention. The Medical Society of Hamburg knows that it is in accord with the whole medical profession of Germany in raising an earnest and vigorous protest against these happenings before the medical fraternity of the whole civilised world.

The above described confinement and treatment of German physicians, who consider it their chief duty in this war, as always, to ensure that friend and foe alike receive medical care, stand in flagrant contradiction to the recognised regulations of the Geneva Convention, accepted by Great Britain, and can have only one result—viz., the withholding from the sick and wounded of a certain amount of skilled attention and so of a chance of relief.

In the name of the physicians of Germany, further, we must protest against the unhealthy concentration of the other German subjects in these camps. The hygiene, shelter, position, provisioning, and cleanliness are such as to awaken nothing but scorn in these men's minds, and seem to reveal an intention on the part of the administration to make defenceless and harmless individuals run the risk of sickness and injury simply because they are Germans.

This fight against the unarmed will not have the slightest effect on the outcome of the war of the nations. Just as Germany is prepared, without one moment of hesitation or faintheartedness, to offer up thousands of her finest men for the honour of the fatherland and for the preservation of her own Kultur, so will she bear this fresh sacrifice, forced on her by caprice and cruelty. She will hold these blameless people who sicken or die like martyrs for Germany's sake and blood witnesses of the level of British morality, as heroes, and honour them as she does her warriors.

The medical profession of England, however, the educated and intellectual leaders of the nation, who in common with the medical men of all countries have, at numerous international congresses—such as the recent Congress of London and the Tuberculosis Congress in Berlin—laid stress on and praised humanitarianism as the chiefest duty of the physician and the highest acquisition of modern Kultur, are in duty bound to redeem their pledges; it is theirs to curb the passions of the populace and as far as they can to prevent the Government from despising that humanity which is recognised in the statutes of all civilisations. The Medical Society of Hamburg therefore requests the physicians of England, as a matter of duty and honour, so to influence the Government as to procure the release of the German doctors and the establishment of hygienic conditions of life in the concentration camps, unless they would, like their Government, bear on their brows the eternal brand of shame.

We await from the medical profession of England an exoneration of themselves in the eyes of the medical profession of the whole world.

Professor BRAUER. Professor NOCHT.
Professor DENEKE. Dr. OEHRENS.
Dr. MARBEN. Professor RUMPEL.
Dr. MARR. Professor SIMMONDS.

Hamburg, Nov. 3rd, 1914.

First-hand investigation of the Newbury Camp contradicts every statement in this open letter. We do not suppose the signatories believed their own words, but they have none the less sent them out in the hope of damaging our national character. We oblige them by publishing their communication knowing that its untruths will be transparent.

THE KING GEORGE HOSPITAL.—The new war hospital for London, an adaptation of the Stationery Office in the Waterloo-road, is being rapidly proceeded with. It will be known as the King George Hospital, and will contain 1500 beds. These will be distributed upon five floors, each storey being completely and separately equipped and staffed. The internal arrangement of the building presents, we understand, no great difficulties, as the provision for lighting, heating, and ventilation is adequate, and there are already lifts. The honorary staff will be drawn from the principal physicians and surgeons in London who are available. A long list of donors of £25 each for the endowment of a bed has been issued. The King has endowed 4 beds, the Queen 2, Queen Alexandra 1, Princess Victoria 1, Princess Christian 1, Queen Amelie of Portugal 1, and the King and Queen of Portugal 2. Cora Countess of Strafford (6), Mrs. Cornelius Vanderbilt (4), and Miss Adele Colgate (2) have given 12 beds to be placed in one ward, Messrs. Courtaulds, Ltd., 10 beds, A. E., 6 beds, and E. S., 5 beds. There are several donors of 4, 3, and 2 beds respectively, while the list of donors of one bed amounts already to 861 names.

WAR AND THE GERMAN MEDICAL PROFESSION.—A correspondent in Switzerland sends us the following notes on medical affairs and opinions in Germany which he has gleaned from German professional journals: "Ten of the new professors in the University of Berlin have been called to the front, but the well-known names of Quincke and V. Noorden appear as lecturers on medicine, and 80 medical students were enrolled up to Nov. 4th. In Berlin, in spite of the rush of medical men to the front, those remaining have less to do than usual. This is ascribed to the previous overstocking of the city in medical talent, and also to the fact that minor ailments have practically disappeared during the war, which has produced among the civil population an 'ability for self-control which will have permanent moral value.' The complaint is freely made that many who remain might be at the front, where many older men were sent in the hurry of the first mobilisation. In East Prussia there is a great scarcity of doctors, and a retaining fee of 25 marks a day is being offered to any who will volunteer. Advertisement is not entirely unknown even under the present conditions of national enthusiasm, and a 'specialist for diabetes' states that, 'contrary to rumour, he has not gone to the front.' The War Office also complains that offers of doctors volunteering for war service are often associated with so many conditions as to be practically worthless. In Vienna the principal building of the University has been turned into an accessory hospital, and the various faculties have had to find other accommodation.

Signs of a more generous reaction from the extreme patriotic feeling at the onset of the war have shown themselves in Germany, and Professor Orth publicly disagrees with the proposed future exclusion of foreigners from working places in the universities; while Professor Waldeyer, the senior of the medical faculty of Berlin, comments unfavourably on the surrendering of foreign medals and of carrying the war spirit over into peaceful fields. The family of du Bois Reymond surrendered his gold medal to the War Victims Fund, in the sense, however, 'of finding no higher imaginable honour for it.' E. von Behring, who surrendered his Harben medal, writes, on the other hand, to explain that his article to celebrate Metchnikoff's seventieth birthday was not withdrawn, but is to appear in another form. Bitter complaint is raised regarding the 'piracy' of German drugs in England and America, especially in regard to salvarsan. The editor of the *Deutsche Medizinische Wochenschrift* is able, however, to console himself with the reflection that the result of salvarsan 'made in England' will be to produce a new 'English disease' which will take a permanent place in English medical literature (it may be recalled that rickets is at present known in Germany as the 'English disease'). A combination of the firms Merck, Böhringer, and Knoll is to manufacture tablet drugs to replace English and French goods.

The *Münchener Medizinische Wochenschrift* quotes its Rome correspondent as saying that no Belgian or French journals had been received since the beginning of the war, and that THE LANCET and the *British Medical Journal* had been received very late and in a much reduced compass, contrasting with the punctual incidence and slighter decrease in volume of its own numbers, and deducing the greater resistant power of Germany to the disturbing influence of the war. The comparison does not, however, hold good, as, comparing at random the second July number with the third October number of the three journals, the German journal was reduced 40 per cent., the *British Medical Journal* 38 per cent., and THE LANCET 29 per cent. only."

EDINBURGH ROYAL INFIRMARY AND THE WAR.—Mr. G. L. Crole, K.C., who presided at a recent meeting of the infirmary managers, referred to the part that the institution was playing in connexion with the war. In addition to providing medical and surgical attendance for the wounded soldiers and sailors, they were doing a large work for the military authorities by practically staffing the military hospital at Craigleith. Sir Joseph Fayrer, their superintendent, was the commandant of that hospital, and with one or two exceptions the medical and surgical staff were all members of their staff. The nursing staff, too, had been largely recruited from the infirmary, 14 having taken service at Craigleith. Three of their assistant surgeons were at present in France, having received leave from the managers to assist in the care of the wounded there. He hoped that the public would take note of these facts and give increased support to the infirmary, which besides its civil duties was doing much in connexion with the care of the wounded.

RED CROSS HOSPITAL IN DUBLIN.—Through the kindness of the Lord Lieutenant, and with the cordial approval of the King, an alternative scheme to that mentioned in THE LANCET last week (p. 1278) for the establishment of a Red Cross hospital in Dublin for wounded soldiers has been rendered possible. His Excellency, with His Majesty's approval, has placed the State apartments of Dublin Castle at the disposal of the City of Dublin Branch of the British Red Cross Society for the accommodation of wounded soldiers. The premises have been inspected by competent medical and engineering authorities and are said to be suitable for the purpose. Very slight structural alterations are required, and there is room for about 450 beds. The scheme will certainly appeal to the public more effectively than that previously outlined. A public meeting in support of it was held at the Mansion House last Monday, under the presidency of the Lord Mayor, and gratifying support in the way of subscriptions was received. It is estimated that a sum of £10 per bed will be required for equipment, or about £5000 in all. About one-fourth of this sum was promised by those present at the meeting. The scheme of management is business-like. There is to be a committee of 20, of whom 10 have been elected by the subscribers, and the other 10 are to be nominated by the medical staffs of the ten clinical hospitals. By this plan the support of the business community and the coöperation of the medical profession of Dublin can be secured. The cost of maintenance will be met by a capitation grant from the War Office. The matronship of the hospital has been accepted by Miss MacDonnell, who had many years' experience as matron of the House of Industry Hospitals in Dublin, and was matron of Lord Iveagh's Irish Hospital in the South African war. No better appointment could have been made.

AUSTRALIAN PRACTITIONERS AND THE WAR.—Our own Correspondent writes: "The medical interest in the European war still continues active. Volunteers were called for to fill the positions in the hospital equipment to be maintained by the Commonwealth Government, and the 100 medical men asked for were many times over available. There are to be two stationary hospitals of 500 beds each, and these will be under the command of Lieutenant-Colonel Ramsay Smith, M.D., of South Australia, and Lieutenant-Colonel T. E. Martin, M.D., of New South Wales. The staff of the first will include Dr. G. A. Syme (Hon. Lieutenant-Colonel) and Dr. H. Maudsley (Hon. Lieutenant-Colonel), of the Melbourne Hospital; Dr. T. P. Dunhill (Hon. Major), of St. Vincent's Hospital, and Dr. S. Argyle (Hon. Major), of the Alfred Hospital. Dr. E. S. Jackson and Dr. J. B. Maclean, of Queensland, will rank as Hon. Majors, as also Dr. J. W. Barrett of Melbourne. Major B. T. Zwar, of Melbourne Hospital, will join the stationary hospital. The senior members of the second hospital staff will be Dr. J. B. Nash (New South Wales) and Dr. J. W. Springthorpe (Victoria), Hon. Lieutenant-Colonels, and Dr. W. H. Read, Dr. W. C. Grey, Dr. P. A. Carter, and Dr. J. M. Stewart as Majors.

Apart from the Expeditionary Forces, many medical men have volunteered for garrison work, and have given service with various troops detailed for coastal defence. Much of this work is no sinecure, as some of the channel ports are of very contracted area, and a fortnight's detention in mid-channel of Hobson's Bay offers no special attraction apart from a sense of duty done. The health of the Expeditionary Forces has been generally good, but there has been a fair amount of influenza and several cases of pneumonia, and measles has also claimed some attention."

THE ETIOLOGY AND PROPHYLAXIS OF TETANUS. Dr. Albert Wilson, who has been serving with the French Army at a military base hospital, sends us the following abridged translation of a recent paper by Dr. Walther in *La Presse Médicale*:—"Out of one group of 135 wounded French there was not a single case of tetanus. Among 270 wounded Germans there were 19 cases. In one case it was a bullet wound; in the other 18 *éclat d'obus*, i.e., shrapnel. All had been wounded on Sept. 6th, 7th, or 8th at the battle of Marne, chiefly on the plateau of Barcy. They had been left behind in the ambulances by the retreating Germans, and received neither food nor care for three days. Rescued by French troops, they arrived at Val-de-Grâce on Sept. 11th to 14th. They had large infected and gangrenous wounds. Out of 51 French wounded in the Hospital de la Pitié there was one case. He was wounded at Soissons on Sept. 15th. He had an injection the same night of antitetanic serum. On the 24th he had trismus, convulsions, &c., and died the same day. One of the Germans received on Sept. 13th was already in tetanus and died on the 14th. Of the 19 cases the incubation period varied from 6 to 16 days; 5 were 8 days and 5 were 9 days. Those who had a short incubation died rapidly and *vice versâ*. In these there was trismus, dysphagia, profuse salivation, tonic contractions with clonic crises, but no great rise in temperature. The treatment consisted in large doses of chloral, hot water in rectum, chloroform, injections of analgesine and antitoxin 20–60 c.c., sometimes intravenous. Out of 20 cases which had prophylactic injections of 10 c.c. one case developed tetanus the next day."

GERMAN SURGEONS AND THEIR WOUNDED.—The German medical papers are naturally largely occupied with the treatment of wounds. Some idea of the magnitude of this task may be gathered from a communication of Excellenz von Schjerning from the front, stating that 9000 doctors are in the field, and that in one week from the western field of war alone 40,000 to 50,000 slightly wounded soldiers were sent home—i.e., omitting the severe and fatal wounds. The emergency dressing of vioform gauze supplied to the soldiers is reported to be very satisfactory on the whole. In one instance only three out of 400 wounded showed any sign of suppuration after 50 hours or more in an ambulance train. The proportion of bullet wounds is strikingly greater than that reported on the side of the Allies; in some cases three-quarters of the wounds were due to this cause, and only a quarter to shrapnel and shell injuries. The question of explosive bullets is abundantly discussed, and in many articles in the German medical journals their use is considered proven by the occurrence of a small entering puncture and a large wound of exit. For the most part the bullet itself is missing or has been extracted before coming under the surgeon's notice, but a certain number of illustrations of spread bullets are given, all of which, it may be observed, are diagrams and not actual photographs. More recently articles have appeared describing the explosive action of the German infantry "S" ammunition at short range. Professor Nippe (Königsberg) has described some striking examples at 10 metres distance where whole vertebræ were comminuted. But perhaps the most interesting note is taken "from the private letter of a prominent Swiss University teacher" stationed at Strasburg, who is doubtless the well-known surgeon Sauerbruch, of Zürich. He writes: "The question is undoubtedly hard to decide *as the appearance of the wound affords no proof of dum-dum*, a fact which I can confirm by personal observation of French soldiers who have been struck by German bullets. Besides this, I have seen a German steel-mantled bullet so spread and transformed by traversing an obstacle as to suggest dum-dum." Professor Schlange, attached to the 19th Army Corps, also states that infantry wounds at 100 metres gave the impression of dum-dum, but were really due to shortness of range; and Professor Köhler (Berlin) speaks of the hydrodynamic action of bullets at short range, whilst at a very great distance there is again a tendency to produce large irregular wounds. The latter effect occurs with especial frequency with modern pointed bullets, which have a tendency, even with very slight resistance, to oscillate and turn broadside on. These authoritative statements may be considered practically to settle the question of dum-dum on the German side, except as a political weapon.

In discussing the effect of ordinary bullets, Köhler considers that on the whole the modern bullet does not differ much from the older blunt one, except in the smaller effect when only soft parts are struck; in this case the soldier is put out of action for such a short time that a further "reduction of calibre below 8 millimetres is not advisable." Whilst ordinary septic infection has been rare in the case of bullet wounds, more serious infections have often been observed with the extensive injuries from shells. In these a rapidly spreading "gas-phlegmon" was at first frequently observed, with a mortality of 85 per cent. The suggestion of Müller (Rostock) to treat these with subcutaneous injections of oxygen gas is said to have markedly reduced the mortality. For the avoidance of anaerobic infections in general hydrogen peroxide is widely recommended, especially in the solid form, which can be powdered on the wounds like iodoform. The perhydrit of Merck and the pergenol of Byk have proved convenient forms. The other serious anaerobic infection, that of tetanus, although not occurring in a large percentage of wounds, has had a high case mortality, and its treatment occupies a large place in the columns of the papers. There has been up to recently a lack of sufficient antitetanic serum, regarding the utility of which when available there is practical unanimity. Von Behring states that 20 c.c. are generally sufficient for preventive treatment, whereas after spasm has occurred at least 100 c.c. should be given intravenously, and if this is ineffective an injection into the nerve trunks from the infected part after dissecting these out. Intradural injection is not sufficiently warranted in theory or in practice. Kocher (Bern), amongst others, warmly recommends the routine trial of $MgSO_4$ injections to mitigate the spasm, but only subcutaneously; and this drug is generally combined with morphia. More potency has been ascribed to luminal, a phenyl-veronal derivative manufactured by Bayer. At the naval hospital in Hamburg great success has attended in several cases the combination of antitoxin with salvarsan. Alternative methods of treatment have a heightened importance by reason of the limited supply of antitoxin available.

For the treatment of ordinary wounds an economy in dressings is urgently recommended, and to this end mastisol has been largely employed to fix the dressings and so avoid the use of bandages. Mastisol, introduced some years ago by Dr. von Öttingen, is a Berlin proprietary preparation consisting of a solution of mastic and other resins in benzol, with the addition of a small quantity of an ester and some colouring matter. A high pharmaceutical authority recommends its replacement with dammar dissolved in benzine at less than one-fifth the price. The resin lodges in the pores of the skin and is supposed to prevent the cutaneous organisms from coming out and infecting the wound without the disadvantage of sealing it completely as collodion would do. Instead of cotton-wool, the supply of which is strictly limited, wood-wool is largely in use, and the tide has turned in favour of the use of charpie (which has been ascertained to take up six times its weight of fluid), so long discarded, enclosed in gauze bags and carefully sterilised. For infected wounds roasted sawdust and peat moss are also in use, except where the open treatment is available as at a base hospital. In septic wounds the internal use of mercury has many adherents.

ASIATIC CHOLERA IN AUSTRIA.—The epidemic of cholera in Austria is on the increase, and has now attacked the inhabitants as well as the soldiers. 844 cases in Austria and 532 cases in Hungary were officially announced in the week from Nov. 1st to Nov. 7th, says one of our occasional correspondents. The mortality of the Austrian cases was 331, or a percentage of nearly 40. In Vienna 90 cases were notified, in Galizia 584 cases. During the previous fortnight, according to the *Bulletin Sanitaire Suisse*, 983 cases of cholera were notified in Austria and 609 cases in Hungary, making a total of 1592. Adding to these figures those for the first week of November we obtain a grand total of 2968 cases notified in the Dual Empire in three weeks.

Vacancies for Medical Officers.—We are asked to announce that the 2nd Northumbrian Field Ambulance, R.A.M.C. (T.F.) is urgently in need of medical officers for the reserve unit. There may be one or two vacancies in the foreign service unit for officers desiring to go abroad. Officers joining for the period of the war only will receive £30 outfit grant, and those joining as ordinary Territorial officers will receive £40. The pay on joining as lieutenant is 14*s.* a day, plus field allowance of 3*s.* a day while under canvas. Applications should be sent to Lieutenant-Colonel D. A. Cameron, commanding 2nd Northumbrian Field Ambulance, R.A.M.C. (T.F.), Bensham, Gateshead.

The British Fire Prevention Committee and the War.—This committee has been largely engaged during the past three months on work connected with the war emergency. Its well-known series of "Fire Warnings" has been extended to meet the special circumstances of the present time. Thus the distribution of the "Warning" dealing with the necessary fire precautions in military hospitals already exceeds 10,000, while abbreviated French and Flemish translations are provided in the form of short notices for Belgian wounded. To meet the fire danger due to the great influx of refugees, many of whom are not familiar with the English open fire, gas lighting, or electricity, a special "Warning" was issued for refugee homes and hostels, and this was also published in French and Flemish. The necessity of conserving all agricultural produce led to a further "Warning" being issued as to fire precautions for farmers. The committee also organised a special fire survey force which is doing a considerable amount of survey work in connexion with Government establishments, and particularly in connexion with hospitals for the wounded. Further, to meet the emergency of the depletion of actual fire brigade and watching staffs, a special fire service was formed with Lord Londesborough as honorary commandant, comprising 300 fire brigade officers, patrolmen, and firemen, divided into sections available for mobilisation at 48 hours' notice. A technical inquiry office has also been formed. The British Fire Prevention Committee is thus devoting the results of its experience very largely to national purposes without interrupting to any considerable extent its ordinary duties.

The American Women's Hospital, Paignton.—This institution has now been opened for more than six weeks, during which time over 400 wounded soldiers have been admitted, and at present there are about 160 patients in the hospital. The Queen recently paid a private visit to the wards.

Dr. Henry Jellett, Master of the Rotunda Hospital, has left Dublin to take charge of a motor ambulance with our forces in Flanders.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

Parliament has adjourned, the House of Lords until Jan. 6th and the House of Commons until Feb. 2nd. Unless any event calling for the urgent attention of Parliament arises in the interval—and in that case the House of Commons could be immediately summoned—the ordinary business of the session will not be entered upon until February. The attention of both Houses during the sitting just concluded has been devoted to emergency matters arising out of the war. Special statements on the military and naval situation were made by Lord Kitchener and Mr. Churchill. Mr. Tennant, the Under Secretary of State for War, made a speech to the House of Commons last week, in which he dealt with many of the problems arising out of the treatment of the wounded in the war. It is worthy of attention.

HOUSE OF COMMONS.

Wednesday, Nov. 25th.

London Panel Chemists.

Mr. Touche asked the representative of the National Insurance Commissioners why a deduction of 40 per cent. had been made by the Insurance Committee for London from the accounts of panel chemists for the month of August; was he aware that in the case of those chemists who used first-quality drugs a deduction of 40 per cent. was more than the profit made; and would anything be done to protect these men from unmerited loss.—Dr. Addison replied: The honourable Member is under a misapprehension. Any such monthly payments as those to which he refers are advances only on account of the total remuneration due to each chemist in respect of the whole year. The rate at which these advances are made is a matter for agreement between the Insurance Committee and the committee representing the panel chemists, and does not necessarily bear any relation to the actual remuneration payable.

Thursday, Nov. 26th.

Recruits and Defective Teeth.

Mr. Boyton asked the Under Secretary of State for War whether he was aware that a number of recruits were suffering from defective teeth, and, if accepted, this led to early disablement, particularly when serving at the front; and whether the War Office would appoint dental surgeons at the depôts, who would give the necessary preliminary attention to this branch of the health of the Army and Territorial Forces.—Mr. Tennant answered: I am aware, of course, that defective teeth are common amongst recruits as amongst other categories of persons. General officers commanding are already empowered to spend money on any man's teeth to fit him for service. A large number of dental surgeons and dental institutions have patriotically arranged to treat, free of charge, recruits who would otherwise be rejected on account of their teeth. I gladly recognise what has been done in this respect. Finally, dental surgeons are being appointed to all the larger military stations at home. They will devote their whole time to work with the troops.

Highlands and Islands Medical Service.

Mr. Ainsworth asked the Secretary for Scotland whether the Highlands and Islands (Medical Service) Committee had completed its report, and, if so, what was the cause of the delay in issuing it and giving effect to its recommendations.—Mr. McKinnon Wood replied: The Commissioners have submitted a scheme which is at present under consideration of the Treasury.

Treatment of Wounded in the War.

In the course of the debate on the third reading of the Consolidated Fund Bill,

Lord Robert Cecil raised questions connected with the treatment of the wounded in the war. He asked for particulars as to the steps taken to deal with them at the firing line, at the clearing station behind the firing line, and at the base hospital. Was the supply of nurses sufficient? He did not raise these matters for the purpose of criticising the Government. What he wanted was information. Amongst all the corps which had done heroic service to the State there was not any which had done more heroic service than the Royal Army Medical Corps. The courage and devotion of its members were absolutely beyond the possibility of praise. Were there enough of them?

Mr. Douglas Hall asked whether antiquated horse-drawn ambulances were still used for bringing troops from the trenches. It was all very well for Lord Knutsford to say that he had seen good hospital trains. There were good ones, but he (Mr. Hall) had seen dozens and dozens coming in in which the wounded were still lying on straw in horse boxes. A great effort ought to be made to get more hospital trains fitted up. He was told by medical men that straw was one of the worst things on which a wounded man could lie, because the germ of tetanus was a horse germ which was contained in manure, and if care was not taken to protect the men they might contract the disease through the medium of the straw. He asked if the Royal Army Medical Corps had considered the feasibility of conveying the wounded away from the front by means of barges on the canals and waterways of France? In the area of fighting there was a fine system of canals through which the wounded could be brought to Calais and Dunkirk. Barges would make an ideal form of conveyance, and eight or nine large ones, with the necessary medical men and nurses, would provide a floating hospital for over 400 wounded.

Sir Frederick Banbury said that a certain number of the wounded, after receiving first aid, had been passed on without further attention to a base hospital. In one case the wound of an officer was not dressed until the third day. The wound was slight, but a piece of cartridge cloth was found in it, and blood poisoning set in causing the officer's death. If the wound had been properly dressed he would not have died. He believed that there had been many cases of that sort. He thought that possibly that might be remedied by the engagement of a larger number of nurses and doctors as near to the firing line as possible. For some time after the war broke out there were no female nurses at the clearing hospitals. He did not doubt that the hospitals in hotels at Boulogne were very efficient, but he feared that they were not sufficient to cope with a sudden influx of wounded. There were two other hotels at Boulogne which might be taken, and also further houses.

Testimony to the Work of the Royal Army Medical Corps.

Mr. Tennant (Under Secretary of State for War), in the course of his reply, said: I now come to the question of the treatment of our brave soldiers returned from the war. May I offer the thanks of the Army Council to the noble lord for the admirable manner in which he has been discharging the most onerous duties in helping the British Red Cross Society, and may I say that I understand that a continuance of these services will be very much appreciated. The noble lord had asked me what are the arrangements for the treatment of the wounded at the front and whether immediate steps are taken upon a soldier being wounded for his proper and careful treatment. I am sure that the House will realise that that can only be answered on the supposition that military exigencies of the case admit of the men being taken away from the firing line at the moment of the injury and then treated, so that the question of the immediateness or otherwise of the treatment is really a military question and not a medical one at the moment. The noble lord has borne eloquent testimony to the wonderful courage with which the officers and men of the Royal Army Medical Corps have discharged their duties—a testimony which I am sure the House will wish to endorse—work which we in the War Office cannot praise too highly. Therefore I think we may carry some hope in our mind that everything possible is done in order that the wounded shall be treated effectively at the earliest possible moment. I should like to give the assurance to the House and to the country that we have an ample number of R.A.M.C. officers and men. The medical and surgical treatment of the troops is in very high and competent hands, as the R.A.M.C. supply a number of officers of the most highly skilled and trained character, and they produce as fine surgeons and doctors as any other branch of the medical and surgical service. We do not limit ourselves entirely to the military medical profession. We have numbers of distinguished members of the medical profession from the civil side as well, distinguished physicians with whom are associated clinical authorities. In addition to that we have bacteriologists engaged in endeavouring to solve some very, very difficult problems. In this connexion I think the noble lord will be interested to know that the wounds are inflicted almost entirely by shrapnel, and, as everybody knows, the vast majority of the wounds are wounds of an almost novel type, and nothing like them has been seen during the recent history of medical science. You have to go back to the days of the Crimea to find anything similar. In the course of the treatment of these wounds there have been differences of opinion on scientific grounds as to what the treatment should be. There is an antiseptic school and an aseptic school. The aseptic school at the beginning of the war was in the ascendant, and now we have had to go back to what was considered a rather antiquated form of treatment by many people. I do not pretend to presume to give any opinion, but the antiseptic treatment is being used so much that we are now engaged in sending out to every soldier, private as well as officers, fighting, a small amount of iodine, in order to give immediate treatment to the wounds when it is possible for the men to do this.

Mr. Douglas Hall asked whether a supply of the serums had been sent.

Mr. Tennant: I cannot answer the honourable Member just now. Nor have we limited ourselves to conducting this work in the established hospitals.

The Evacuation of the Wounded.

We have established a travelling bacteriological laboratory and also a small laboratory for sanitary purposes. Bacteriologists have been doing work which is bearing great fruit. I would like also to mention that the Royal Army Medical Corps are working in close connexion with the Lister Institute and the Research Committee of the National Insurance and other institutions. Let me deal for a moment with the question of nurses and clearing station. The honourable Member (Mr. Douglas Hall) I think made out one move more than I could account for in anything which we know of at the War Office. When a man is wounded his wound is dressed as near to the firing line as may be, and he is then taken to the clearing station and from the clearing station to the train which takes him to the base. Thus there are three moves, and not four. I think if the honourable Member has different information from that it must have been in the early stages of the war. It is perfectly true that things did occur in the early stages which, as I am sure the noble lord knows, do not occur now, and no doubt on a tremendous military occasion of the most dangerous and difficult nature which occurred in the early stages of the war that degree of precision of treatment which you can have when you have fixed trenches could not be attained under such circumstances. I feel sure that that will be fully appreciated both inside the House and outside of it. There is an ample number of nurses in the clearing station. They do not get nearer to the firing line than the clearing station. Not only is there a sufficient number, but there is a waiting list. There are in France, I may say, roughly speaking, because I am not certain of all places, nurses held in reserve.

Mr. Douglas Hall: Since when have there been nurses at the clearing hospitals?

Mr. Tennant: I am afraid that I cannot give the date. I will get the information. There is an ample number now. I should like to make it quite clear that we have an ample supply both of personnel and of material, because I have seen it stated that subscriptions are being raised in order to secure such articles as chloroform. I have here a telegram received yesterday from the honourable and gallant Member for Fareham (Mr. A. Lee). who has been doing very fine work for the State in inquiring into and reporting to us upon this very subject of the treatment of the wounded. It states: "I am informed that the St. John Ambulance Society has issued an appeal for £100,000 to purchase chloroform and other medical stores, stating that operations on our wounded are being performed without anæsthetics. Can assure you on the highest authority this allegation is totally untrue both as regards the present and the past. Suggest that it should be denied in Parliament to-day in order to allay public anxiety and to stop subscriptions to quite unnecessary fund." I think that that statement, coming from the source it does and so immediately, will carry conviction to the minds of the House. Not only are all demands complied with but they are anticipated. The next point is the removal of the wounded from one place to another and the circumstances in which it occurs. The honourable Member (Mr. Douglas Hall) asks why we have so many horse ambulances. I may inform the House that we have three horse ambulances for every seven motor ambulances. The necessity for having horse ambulances is that there are parts of the country that horses can get over and motors cannot because of the mud. You really cannot get mechanically propelled vehicles over some parts of the country which can be traversed by horses. Therefore we have horse ambulances in that proportion. We are now replacing nearly all the horse ambulances by motor ambulances from the front to the rear. It has been suggested, not in this debate but in the press, that we have refused motor ambulances. It is not true that we have refused them. All we have said is that we are not ready to accept them just now. We shall no doubt be ready and willing to accept them in the future, and we have told those kindly disposed persons who have been so good as to offer motor ambulances that if they will renew their offers in a month or two months' time we shall be very glad to avail ourselves of them. Hospital trains have been supplied and have been very much improved. I can assure honourable Members that they are very comfortable at present. Three others are being prepared. We are indebted to Lord Michelham and the Red Cross Society for these trains.

Hospital Trains.

That brings me to the conveyance of the wounded—to the question of straw and tetanus. I have a report from the honourable and gallant Member for Fareham (Mr. Lee) stating that tetanus is extremely rare in the army at the present time. With regard to straw, I think that has now been abandoned owing to the improvement in the trains which I have mentioned, but I shall make inquiries. I have never heard of the straw before.

Lord Robert Cecil: Can the right honourable gentleman give us any indication as to the time that elapses normally between the clearing hospital and the base hospital?

Mr. Tennant: That depends upon the train service. I was coming to that and the barge conveyance suggested by the honourable Member (Mr. Douglas Hall). It is very difficult to give a specific reply to the noble lord's question, because the time varies enormously: according to as and when vast numbers of troops and other necessaries are going up. Moreover, the House ought to remember that all the railroads are in the hands of the French Government, and when the honourable gentleman suggests that we should send over from here officers and men versed in railway service, that is not a possibility. We cannot insist upon the French Government taking our servants when they have their own servants there. I would ask the House to appreciate that.

Mr. Douglas Hall: What I suggested was that they should do work which certain other officers do now—that is, to keep the French officials up to the mark and to get what they want. Railway officials know much better than militia officers what is requisite to make a train comfortable.

Mr. Tennant: I am afraid we cannot absolutely insist upon the French Government accepting those whom we choose to send over. At the beginning of the war we did select certain officers who had had experience of those matters, for the most part Army Service Corps officers. They were accepted by the French Government, and are, I believe, doing excellent work now in endeavouring to expedite trains. Of course, the difficulty is prodigious. When you have those enormous masses of men and not very great train facilities it does not require very much imagination to see what a very difficult operation it must be. With regard to the Indian wounded who are necessarily detained in England previous to their departure for India, we hope in a few days to have 3000 beds at Brighton. In the meantime they are comfortably housed at Brockenhurst. Everything is being done to ensure the comfort of the Indian sick and wounded.

Sir J. D. Rees: Is there in the hospital any trouble concerning the food of any of the Indian troops?

Mr. Tennant: I think it is being perfectly done. There has not been any complaint so far as I am aware.

Sir J. D. Rees: I did not suggest it.

Mr. Tennant: I am glad the honourable Member does not. Of course, they have everything specially constructed and a special personnel. We are arranging for the use of mobile hospitals during the winter which we think may be particularly useful. The barge suggestion I confess is quite a new one to me. I shall be glad to lay the honourable Member's suggestion before my medical military authorities, by whom I am sure it will receive the consideration it deserves. Whether it is possible or not is another matter.

Mr. Douglas Hall: A report on the system has been sent to some of the authorities and they have approved of it.

Mr. Tennant: I hope we shall be able to put it in force. The honourable baronet (Sir F. Banbury) informed us of a very distressing case, which I am afraid is only too true, of a wounded officer who came home without having had his wound dressed except for the initial dressing after it was inflicted. I can only express the hope that with the more perfect organisations which we now have there will be no recurrence of such a case. With regard to nurses, I hope I have said sufficient to satisfy the House. I will certainly convey the honourable baronet's statement to the medical authorities, and if there is not room in the other houses the two hotels which he has mentioned will be utilised.

Sanitation: Success of Measures Taken.

I would say one or two words upon a phase of the medical activities which I think the country will consider as important as those with which I have already dealt. I mean the question of sanitation. Every effort has been made to preserve the health of the troops in the field, and so far I may say they have been entirely satisfactory. The sanitary difficulties increase, of course, as the campaign proceeds. We are now endeavouring to see in advance what our requirements will be and to meet them. In this connexion we are preparing divisional sanitary companies, which will consist of sanitary inspectors and men. Yesterday Sir A. Keogh, the Director General of the Army Medical Service, saw the members of a sanitary committee whom he had sent out to the front to examine into a phase of the situation which I told the noble lord in private conversation was causing me anxiety. The committee has just returned from a tour of inspection, and they assure us that nothing could exceed the sanitary condition of the actual trenches at the front. That, of course, is where the danger occurs. I would like to relieve the mind of the noble lord of any anxiety that I may have caused him in that particular. I can assure the House that I myself was greatly relieved by the information brought back by the committee. Of course, every precaution which science and the experience of these gentlemen can suggest has been taken, and the task—I hope it will be fully realised by the House—has been admirably conceived and well carried out. Proof of that is that we have had very few cases of enteric. I do not wish to go more fully into details as to the steps we have taken to preserve the sanitary condition of our soldiers, because I am informed that the statement might be copied by the enemy, and no doubt it is part of the military situation. If they are inefficient in their sanitary arrangements we will not regret it. Therefore, I do not wish to go further into the matter lest I should be aiding the enemy. But who is not liable to be lying awake at night thinking of the terrible hardships through which our troops have to go, and are daily and nightly undergoing, in the titanic struggle which is now going on? Our troops have all the horrors which they have before their eyes, with frost-bites at nights now added, and if the horrors of disease are to be added to all this, then indeed it would be that we were not serving the State in the manner in which the State has a right to expect. We cannot always be certain of these matters, especially as the campaign goes on, and, as I have said, the dangers which confront the troops in the field become greater and greater almost from day to day, particularly when our troops move to the ground which has recently been occupied by the enemy and where there may be all the horrors of decomposition going on. I feel that the House realises the task which lies before us. Honourable Members will know that these are anxious times. I think that Members will be glad to know that so far as this phase of the situation goes we have been successful. We have been successful through the skill, energy, activity, and scientific knowledge of the Royal Army Medical Corps under Sir Arthur Sloggett. I should like the House not to withhold the meed of praise where it is due to men like Sir Arthur Sloggett and Sir Alfred Keogh.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Thompson.—On Nov. 26th, suddenly, in Croydon, Henry George Thompson, M.D., V.D., J.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PRACTICAL GUIDES TO FOOD ECONOMY.

THE issue of special leaflets by the Board of Agriculture and Fisheries should be very widely known at the present juncture, as they invariably contain practical information of the greatest value on questions of food economy. Last week, for example, a series was issued on the harvesting and storing of garden vegetables (potatoes, artichokes, onions, and so forth), on pig-feeding, and the purchase and preparation of food for poultry in gardens and allotments. These valuable leaflets are bound in volumes from time to time, each containing 100. They may be obtained at the office of the Board of Agriculture and Fisheries, Whitehall-place, London, S.W., price 6*d.* each volume, post free. The scheme of issuing these pamphlets is an admirable one, which may save much unnecessary loss and waste of food caused by the lack of good practical knowledge and management.

THE WATER SYMBOL.

To the Editor of THE LANCET.

SIR,—I have read with interest your annotation entitled "Medical Characters in Chinese Writing" in THE LANCET of Nov. 21st, and especially the lucid explanation of the "key picture" system of Chinese characters which indicates the close relationship existing in sense between certain words expressing similar notions. The fact which you point out, that the symbol for water—the waved line—is still used in practical business, is perhaps not so generally familiar as you assume. Of course it is known to those who have ever read a book on astronomy, being the sign of Aquarius or the Water-bearer, and I have by me a photograph of the premises of the Aquarius Mineral Water Company at Shanghai showing a big signboard on the roof with this sign of the waved line.

There is no doubt about the vitality of this symbol. It is to be seen in the cartouches of the names of the Pharaohs and in the Rosetta stone where it is more like MM, and we still see it in our letter N which is its survival.

I am, Sir, yours faithfully,
London, Nov. 26th, 1914. W. W.

BAVARIAN BIRTH-RATE.

Mr. Lucien Buchmann, British Consul at Munich, writes in his annual report:—There were in Bavaria in 1911 215,203 births, in 1912 214,548, and in 1913 207,458. The decrease affects mostly legitimate births, which amounted in the three years to 188,738, 187,423, and 181,187 respectively, whilst illegitimate births remained almost stationary—viz., 26,465, 27,125, and 26,271. Although, however, the Bavarian birth-rate is decreasing, like that of the whole empire, yet the more rational and more careful rearing of children results in a larger percentage reaching manhood than was the case in former years, and there is still a yearly increase of population, but not sufficient to satisfy the demand for labourers at certain seasons. The Nuremberg birth-rate was, during the first six months of 1914, over 8 per cent. less than during the same period of the preceding year.

A NATIONAL CHRISTMAS CARD.

WE have received from Messrs. Raphael Tuck and Sons, Limited, two specimens of their National Christmas card, the entire profits of the sale of which are to be devoted to the Prince of Wales's National Relief Fund. The card consists of a folded cover 7½ × 5½ inches, enclosing a four-page illustrated leaflet retained by a red, white, and blue braid. On the front cover is a coloured reproduction of Mr. Harry Payne's group of the Home, Colonial, and Indian Forces, with naval vessels and aircraft afloat and aloft in background. The leaflet on its third page shows a beautiful photogravure of Mr. Bernard Gribble's picture of a Dreadnought passing and saluting the *Victory*. Altogether a dignified and artistic card, it will surely sell in hundreds of thousands at the modest price of 6*d*.

◆

W. H. G.—The following list of handbooks will prove useful. There is no single book on either of the subjects mentioned by our correspondent, but a great amount of valuable information is contained in the manuals mentioned below. They are all obtainable from Messrs. Wyman and Co., Fetter-lane, London, E.C.

(A) Management of a Field Hospital:
  1. Regulations for Army Medical Service. 6*d*.
  2. Manual of Royal Army Medical Corps Training. 9*d*.
  3. Field Service Manual, Army Medical Service. 4*d*. To which might be added—
  4. Field Service Regulations, Part II. 1*s*.

(B) Commissariat:
  1. Regulations for Supply, Transport, and Barrack Services. 9*d*.
  2. Supply Handbook for Army Medical Service Corps. 1*s*. 6*d*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. J. Gray: The Electrical Conductivity of Echinoderm Eggs, and its Bearing on the Problems of Fertilisation and Artificial Parthenogenesis (communicated by Prof. J. S. Gardiner).—Dr. J. C. Willis: The Endemic Flora of Ceylon with Reference to Geographical Distribution and Evolution in General (communicated by Dr. D. H. Scott, foreign secretary to the Royal Society).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Philip Turner, J. D. Rolleston, Sidney Gilford): at 4.30 P.M.

Specimens and Cases:
Dr. Eric Pritchard: Abscess of the Liver.
Dr. J. D. Rolleston: Cerebral Embolism in Diphtheria.
Dr. E. B. Gunson: Pericarditis in Scarlet Fever.

CLINICAL SECTION (Hon. Secretaries—Thomas H. Kellock, David Forsyth): at 8 P.M.

Clinical Cases:
Dr. Alexander Morison: Case of Precordial Thoracostomy for Heart Disease.

Paper:
Dr. A. F. Hertz and Mr. C. H. Fagge: Case of Spontaneous Gastro-enterostomy with Subsequent Perforation and Recovery after Operation.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Tetanus, with Special Reference to (*a*) Prophylaxis, (*b*) the Serum Treatment of Established Tetanus—Dosage and Method of Administration (opened by Major D. Embleton, R.A.M.C.). Followed by Prof. F. W. Andrewes, Dr. J. Eyre, Lieut. R. B. Blair, R.A.M.C., Dr. C. Browning, and others.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—9 P.M., Clinical and Pathological Evening. Cases and Specimens will be shown by Dr. F. Fox, Dr. T. Thompson, Mr. L. Bromley, and Mr. W. G. Ball. Dr. A. C. Jordan and Mr. R. L. M. Wallis: Demonstration Illustrative of War Injuries.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY—9 P.M, Dr. S. Dodd: Eclampsia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynæcological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham): Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3.30 P.M., Special Demonstration of Cases illustrating the Diagnosis of Disease by Clinico-pathological Methods (Mr. T. H. C. Benians). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. H. Howell: Physiology of the Cerebellum.

FRIDAY.—8.15 P.M., Sir Ronald Ross, K.C.B.: Government and Military Sanitation in the Tropics (illustrated with lantern slides).

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following magazines, journals, &c., have been received:—Homœopathic Recorder, St. Mary's Hospital Gazette, St. Thomas's Hospital Gazette, Revue d'Hygiène, American Journal of Obstetrics, Journal of Tropical Medicine and Hygiene, Calcutta Medical Journal, Canadian Medical Association Journal, American Journal of Tropical Diseases, Archives of Internal Medicine, Ophthalmoscope, Archives of Diagnosis, Dominion Medical Monthly, Journal of the Royal Sanitary Institute, Therapeutic Gazette, South African Medical Record, Medical Journal of South Africa, &c.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. R. J. Albery, Lond.; Dr. E. L. Ash, Lond.; Mr. A. L. Anthony, Gravesend; Alexandra Therapeutic Institute, Lond.; Dr. T. C. Askin, Woodbridge; Messrs. Abdulla and Co., Lond.; Messrs. Anderson, Topp, and Co., Lond.; Messrs. Arnold and Sons, Lond.

B.—Birkenhead Union, Clerk to; British Drug Houses, Lond., Managing Director of; Bury Hospital Board, Clerk to the; Dr. Oswald Briggs, Nottingham; Miss B. F. Board, Almora, India; Messrs. W. H. Bailey and Son, Lond.; British Red Cross Society, Lond., Director of; Breves, Ltd., Lond.; Dr. J. L. Berman, Lond.; Dr. J. W. Barrett, Melbourne; Dr. N. Bardswell, Midhurst; Mr. T. H. C. Benians, Lond.; Dr. W. Blair Bell, Liverpool; Mr. Henry Bazett, Lond.; Mr. H. Butterfield, Northampton; Board of Education, Lond., Secretary of; Dr. Robert Boxall, Abinger.

C.—Mr. H. Curtat, Territet; Dr. M. A. Collins, Epsom; Corbett Estate Office, Droitwich, Secretary of; Mr. R. Collins, Glasgow; Chelsea Hospital for Women, Lond., Secretary of; Mrs. Cox, Reading; Cornwall County Council, Truro, Medical Officer of; Mr. J. F. Colyer, Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Clayton Hospital, Wakefield, Hon. Secretary of; Lieutenant-Colonel D. A. Cameron, R.A.M.C., Bensham; Sir W. Watson Cheyne, Bart., Lond.; Messrs. E. Cook and Co., Lond.

D.—Mr. A. J. D'Souza, France; Messrs. Dawson and Sons, Lond.; Messrs. S. Deacon and Co., Lond.; Dumfries and Galloway Royal Infirmary, Secretary of; Dyspeptic; Dr. Thomas Dutton, Lond.; Dr. Vincent Dickinson, Lond.; Messrs. Duncan, Flockhart, and Co., Edinburgh; Mr. W. T. Dupree, Portsmouth; Mr. W. J. Dredge, Lond.; Sir James Mackenzie Davidson, Lond.; Mr. Percy Dunn, Lond.

E.—Mr. J. Edwards, Manchester; Sir Frederic Eve, Lond.; Dr. L. Wilson Evans, Port Sunlight; Epsom College, Lond., Secretary of.

F.—Messrs. Ferris and Co., Bristol; Messrs. Fannin and Co., Dublin; Dr. Y. Farag, Cairo; Fine Art Society, Lond.; Dr. George Foy, Dublin.

G.—Captain R. L. Gamlen, I.M.S., Jersey; Dr. Major Greenwood, Lond.; Dr. Horace Greeley, Brooklyn; Dr. Edwin Goodall, Cardiff; Dr. Guthrie, Lond.

H.—Dr. E. Hawkins, Birmingham; Messrs. C. J. Hewlett and Son, Lond.; The Howat Complete Advertising Service, Glasgow; Hereford County and City Asylum, Clerk to the; Messrs. Hutchison and Dow, Glasgow: Hudson's Eumenthol Chemical Co., Sydney; Lieutenant-Colonel F. W. H. Davie Harris, Lond.; Messrs. Hilton and Co., Calcutta; Hunterian Society, Lond., Acting Hon. Secretaries of; Dr. E. H. R. Harries, Newport; Mr. J. B. Hurry, Reading; Mr. W. Sampson Handley, Lond.; Captain Henry, Jersey; Mr. J. Hatton, Bath; Mr. H. G. Hirons, Lewes.

I.—International News Co., Lond.; Inverness District Asylum, Clerk to the.

J.—*Journal of the American Medical Association*, Chicago; Jeyes' Sanitary Compounds Co., Lond.; Dr. I. W. Joynt, Lond.; Lady Jellicoe, Lond.; Messrs. Walter Judd, Lond.

K.—Messrs. H. S. King and Co., Lond.; Kensington and Fulham General Hospital, Lond., Secretary of; Dr. H. W. Kerfoot, Penetanguishene, Canada; Dr. Robert Knox, Lond.; Major D. C. Kemp, I.M.S., Vellore; Kent and Canterbury Hospital, Canterbury, Secretary of; King Edward VII. Memorial Sanatorium, Shrewsbury, Secretary of; Kent County Asylum, Maidstone, Clerk to the; Mr. P. E. Kingsford, Lond.

L.—London Colony for Epileptics, Epsom, Medical Superintendent of; Mr. H. K. Lewis, Lond.; Liverpool Corporation, Clerk to the; *La Radiologia Medica*, Milano; Leeds General Infirmary, Secretary of; Professor Harvey Littlejohn, Edinburgh; Major J. C. Holdich Leicester, I.M.S., Southampton; Messrs. E. and S. Livingstone, Edinburgh.; Dr. R. Bruce Low, Lond.

M.—Sir J. McFadyean, Lond.; Dr. D. M. MacRae, Clocolan, South Africa; Maltine Manufacturing Co., Lond.; Fleet-Surgeon G. E. THE LANCET, December 12, 1914.

The Croonian Lectures
ON
MODERN ASPECTS OF CERTAIN PROBLEMS IN THE PATHOLOGY OF MENTAL DISORDERS.

Delivered before the Royal College of Physicians of London,

By EDWIN GOODALL, M.D. Lond., B.S., F.R.C.P. Lond.,
MEDICAL SUPERINTENDENT, CITY OF CARDIFF MENTAL HOSPITAL.

LECTURE II.*

Sir Thomas Barlow and Gentlemen,—The beneficial results which follow upon the administration of a reliable preparation of thyroid gland in certain forms of mental disorder, of which in my first lecture I gave illustrations, are not merely gratifying in themselves, but are to be welcomed as affording incidentally a striking demonstration of the dependence of such conditions upon defective metabolism. Furthermore, these results have been the means of directing the attention of those engaged in the endeavour to elucidate the pathology of the psychoses to the functions of the glands with internal secretion in relationship to states of mental alienation.

The Ductless Glands and Mental Disease.

Very seldom is one's attention drawn in actual psychiatric practice to these glands, and practically to the thyroid alone, because the insane patient presents the symptoms of myxœdema or Graves's disease. The dependence of the psychosis in such cases upon the defect or disease of the thyroid gland is proved not only by the effect of medicinal treatment, but in the case of Graves's disease by that of surgical interference. Delmas[1] records a case of insanity in Graves's disease in which the psychosis disappeared three months after the operation of hemi-thyroidectomy, and a similar case is recorded by Horand and others.[2] Such instances as these, with the fact that mental disturbance occurs during thyroid treatment in predisposed persons and ceases with cessation of such, do away with the theory that the psychosis and the Graves's disease are merely concomitant and dependent upon a common cause. Actual insanity is very rare in diseases of the adrenal gland; I have only seen one case of insanity with Addison's disease, though psychical changes are known to occur. In the absence of notes I do not refer to the symptoms, but Porter Phillips[3] describes mental symptoms which pointed to neurasthenia or dementia paralytica in a case under his notice; further developments led to the correct diagnosis of Addison's disease. In a case of carcinoma of the adrenals, described by Rodinow,[4] the mental condition was that of a patient with insanity of persecution.

The work done upon the morbid anatomy of the ductless glands in mental disorders has elicited the following few facts. It is especially in epilepsy with insanity that changes are found, in the thyroid, parathyroid, pituitary, and suprarenal glands, and these are of the following general nature: to the naked eye, shrinkage, asymmetry, diminution of weight; histologically, sclerosis, with hyperæmia, or even hæmorrhagic infiltration, shrinkage of acini, diminution of colloid, proliferation of the lining epithelium of the acini. Briefly, shrinkage of the gland and replacement of essential (parenchymatous) tissue by fibrous tissue, nothing of a characteristic or peculiar kind. This morbid condition of some or all of the ductless glands in epilepsy with insanity, but especially of the thyroid, has been found in all cases as yet examined by the various workers who have reported on the subject.[5] In respect to dementia præcox and manic-depressive insanity there are no uniform results, and there is no sufficient evidence that any of the glands of internal secretion are diseased. In confusional states anatomical evidence of degeneration of function of the thyroid, hypophysis, and adrenals has been recorded (Parhon and others), but requires corroboration. In respect to dementia paralytica, de Albertis and Masini[6] record their results in 20 cases in respect of the thyroid gland checked by numerous controls; in about 75 per cent. there were similar changes to those given above. The function of the gland was, in their view, wholly or in part abolished. But it has to be borne in mind that sclerotic changes may and do occur in other organs, such as the liver and kidney, in chronic cases of insanity. It is clear that the work done upon this subject is much in need of extension, amplification, and control by means of parallel observations upon sane persons of the same age who have died from the same common maladies as the insane persons examined; control further, by examination of other organs in the same person, such as the heart, liver, and kidneys. Gorrieri[5] is one of the few writers with whom I am acquainted who have proceeded on these lines, making numerous controls in sane persons, and he finds that anatomical changes in the ductless glands are more frequent in the insane in respect to epileptic insanity. Further, Amaldi[7] found lesions of the thyroid in 56 per cent. of 107 individuals suffering from various (the most diverse) forms of insanity, as against 32 per cent. of 22 sane controls. Evidence of hypoplasia of the ductless glands in cases of defective brain development, more pronounced than hypoplasia of the organs in general, has not been furnished, not sought for even, that I am aware of.

Toxicity of Fluids in the Insane.

This point has not been systematically inquired into, and there are very few observations of value. One reads, and more especially hears, a good deal about "toxins" in the psychoses, but the familiarity with which the term is used is not based upon pathological and chemical research. Such work as has been done has mainly been with the fluids of epileptics, no doubt on account of the interest attaching to the problem of the epileptic seizure.

Blood Serum and Cerebro-spinal Fluid; Urinary Colloids.

Although I have not worked directly at the problem of the toxicity of the body-fluids in the insanities, I have, in conjunction with my friend and co-worker, Dr. H. A. Schölberg, inoculated intravenously 80–90 rabbits with the blood serum and cerebro-spinal fluid of pronounced cases of dementia paralytica and the blood serum of recent and chronic cases of dementia præcox. This work I shall refer to in connexion with the subject of the production of precipitin and antibody, as it was carried out with a view to studying

---

* Lecture I. was published in The Lancet of Dec. 5th, 1914, p. 1287.

No. 4763.

such production, and not with a view to studying toxicity. It will suffice here to say that the serum was employed in doses of from 2 to 3·5 c.c., and in total amount as much as 42 c.c. were injected, spread over a period of weeks up to 19 weeks, in bi-weekly doses. The cerebro-spinal fluid was used in doses of from 2 to 8 c.c.; in total amount as much as 19·5 c.c. was injected during a period of one month. Of 84 animals, 28 died in the course of these injections, or 33 per cent.; excluding a few which died in anaphylaxis and from accidental causes, I should put the number dying from an unknown (? toxic) cause at 25 per cent. The majority of these showed great, sometimes enormous, wasting, whether injected with blood from cases of dementia paralytica or dementia præcox. Convulsions were not observed. The animals injected with serum from dementia præcox cases died to about an equal extent with those injected with serum of general paralytics. The numbers injected with cerebro-spinal fluid were much fewer, but no deaths occurred in them. Pilcz [8] found that white rats, after injections of 2–3 c.c. of serum from general paralytics, were not apparently affected, and he cites Pappenheim as observing the like in a rabbit which received 9 c.c. of cerebro-spinal fluid from a general paralytic.

As regards toxicity of the blood of epileptics, Meyer's [9] experiments go to show that there is room for further research in order to elucidate the facts. He failed to produce any symptoms in 10 out of 11 guinea-pigs injected intraperitoneally with 10–15 c.c. of defibrinated blood taken from normal persons, the eleventh dying after convulsions. Of 10 guinea-pigs injected with blood removed during an epileptic seizure, nine had typical tonic-clonic convulsions in from one to five hours after injection. Blood taken in the interval affected the animals according to the time which had elapsed since the last seizure and to the severity of the disease; sometimes there were seizures and death, sometimes there was death, at other times no result. But a second injection with the seizure-blood two to four days after the first did not produce the same results as on the first occasion. There are some grounds for the view that the toxic substances in such conditions are colloidal in nature, and more precise results might be obtained by injecting adialysable substance alone. The experiments of Loewe [10] upon urinary colloids in epileptics and in the insane support this view. He reduced the adialysable substance of urine *in vacuo*, treated it with alcohol, and dried the insoluble portion in an exsiccator; the latter keeps for many months in sealed tubes. Loewe claims that the adialysable substance is increased in epileptic urine, and that it is rich in phosphorus-holding compounds, but these important points need further investigation, especially as the increase is not limited to epilepsy, but occurs also in the katatonic phase of dementia præcox, in dementia paralytica—although after seizures—and in delirium tremens. The essence of Loewe's research, however, is his statement that, whilst the adialysate in the psychoses mentioned is highly toxic, it does not produce seizures, whereas in epilepsy it is not only toxic (chiefly in connexion with the epileptic convulsion), but produces seizures very like epileptic ones when injected intravenously. Similarly produced exsiccate from the urine of normal persons is not toxic.

Chronic Renal Disease.

Whereas mental disorders associated with morbid conditions of the ductless glands, and proved to be caused by such, might be classified as disorders of metabolism or of auto-intoxication, there are other cases in which the theory of an auto-intoxication appears more reasonable; as, for example, the case of insanity occurring in chronic renal disease, or with morbid conditions of the gastro-intestinal tract. With chronic renal disease there occasionally occurs such definite mental alienation, amounting sometimes to systematised insanity, that institution care becomes necessary. As with the disorders of mind due to the specific fevers, so with those due to kidney disease: there is no characteristic syndrome. States of confusion and stupor, hallucinations, delusions of persecution, delirium, temporary conditions of agitation or of exaltation—such are the common symptoms. The clinical picture is liable to be complicated by somatic disorders due to focal lesions in the brain. Thus the suggestion of dementia paralytica may be raised. But *vice versâ*, as was well shown by the younger Bristowe some years ago, cirrhosis of the kidneys is very frequent in dementia paralytica; yet in the absence of detailed and systematic study of other vital organs, including the ductless glands, too much weight must not be laid upon this fact. It is noteworthy that in chronic renal disease, as in the infection-psychoses, katatonic symptoms may occur; such cases are described by Bischoff and Ascoli.[11] Improvement in the renal condition brings about the like in the mental disorder in these cases of renal origin. The mental disorder which is sometimes seen in patients in whom there are foci of disease is ascribable to auto-intoxication, since it passes away on removal of such foci. Picqué [12] records two instances—the first, that of a young woman who, after months of confusional insanity, was cured by appendicectomy; the second, a patient with melancholia and hypochondriasis who had chronic prostatitis and was cured of the mental disorder by prostatectomy.

Constipation.

A great deal has been said and written upon the subject of auto-intoxication psychoses due to infection from the gastro-intestinal tract, and there is no doubt a widespread tendency to look upon the affective disorders, more especially, as in some instances either themselves or in respect of certain of their phases or exacerbations originating in disturbances of the gastro-intestinal functions associated with constipation. Apart from the common experiences of everyday life, there is more particularly the experience of the effect of purgatives in recent cases of insanity and in the exacerbations of chronic insanity. Recent cases received into institutions for the insane are very frequently constipated to an extraordinary degree, and when the constipation is at length overcome, and long before the effects (if any) of rest and special diet have had opportunity to become manifest, it is very frequently observed that the acuter mental symptoms, those which caused anxiety before admission or trouble after admission, have passed away. In passing I would state my opinion that acute and recent cases of insanity do not require special diet; they require their ordinary diet and extras in plenty. Practical experience justifies this view; exceptional instances, of course, occur; apart from these there is, in my belief, no reason for the milk diet which these patients are by some subjected to. That such symptoms as mental depression, irritability, impulsiveness with violence, inability to fix attention and to work at the customary task, a stuporose state, occur amongst chronic cases of insanity, and are removed by an efficient purgative, is known to every experienced mental nurse. More interesting is the pyrexia which sometimes accompanies these manifestations. One meets with cases of secondary dementia, or of recent insanity passing into dementia, patients not able to express their feelings, noticed by the nurse to be mentally changed, or to look ill, or to refuse food, or abstain from work; upon taking the temperature the thermometer records 103° or 104° F. Drastic purging reveals extreme constipation, and is followed by rapid subsidence of the symptoms, including pyrexia. This picture is highly suggestive of a toxic substance acting upon an unstable brain; it appears to furnish a pure instance of a somatic disturbance inducing a psychical one. Many like myself there must be who have never seen a case in which mental disturbance antedated the somatic disorder which exists in cases of insanity; we do not see the patient at the commencement of the mental illness. I would expressly state that I am not denying that the sequence of events may be as stated; but I should require thoroughly reliable information, based upon a medical examination of the alleged instance of psychical causation at the date of the earliest mental symptoms, before crediting this explanation, and even then one would need to know something of the medical history of the patient for, say, three months before the appearance of symptoms, including information as to weight changes.

Disorder of the Gastro-intestinal Functions.

To return to my theme: Plönies[13] has described several cases in which psychoses, mostly characterised by hallucinations, imperative ideas, and depression, were due in his view to disorders of gastric digestion, objectively associated with tenderness to percussion over the gastric region and dilatation of the stomach. At any rate, mental disorder disappeared upon suitable treatment of the gastric condition. Hudovernig[14] gives the case of a man, aged 30 years, sent to the surgeon for appendicitis, and transferred to the psychiatric clinique. He showed acute confusion, with hallucinations, ascribed to some intestinal disturbance. Castor-oil was followed by foul-smelling stools; thereafter the mental disturbance passed away. His history, subsequently ascertained, showed that four days before admission to the surgical clinique he had partaken of sausage and sauerkraut, upon which the illness had supervened. Such cases as those of Plönies, especially, indicate the need for more scientific and systematic physical examination of the insane; I do not believe that under the existing system in mental hospitals anything approaching to adequate examination, including the application of the methods of the clinical laboratory, is made. I believe that this is one of the matters which will not be righted until psychiatric cliniques, as seen abroad, are established in this country. The examination of the stools in cases in which early symptoms of mental disorder are observed and in cases of periodic attacks or exacerbations should be part of the ordinary routine; the amount of the stools in 24 hours, their consistence (hard, dry, semi-liquid, membranous), their form (normal, or in scybala, or pellets), their colour, odour, and constitution (whether containing undigested food or not)—these are points for observation. Pardo[15] shows that the rate of transit of the intestinal contents is very greatly delayed in recent and acute cases; carmine mixed with the food is not all evacuated in 24–48 hours, as in healthy people, and in the patients themselves when well. Further, the dye appears, not continuously, as in health, but irregularly at intervals. Benigni[16] studied the intestinal functions in 50 cases of insanity of various kinds, the patients being upon a fixed diet, according to the method of Schmidt and Strasburger. He found disorder of one or more of the digestive functions in rather more than one half of the cases; protein digestion especially was incomplete, but the conversion of starch and fat was so also. The residual content of the fæces gave evidence of incomplete digestion.

Indicanuria.

The presence of indigo-producing substances in the urine of the insane has for long been a subject of interest, upon the supposition that their presence in excess pointed to toxæmia of intestinal origin. The teaching in respect to the mode of origin of these substances has in effect been that, by the splitting of proteins in the digestive tract, indole is ultimately formed and through the agency of bacteria; that this is absorbed through the intestinal mucosa into the system; that it then undergoes oxidation into indoxyl, which by synthesis ultimately becomes indoxyl-potassium-sulphate or indican, which is excreted by the kidney. This substance on oxidation yields indigo. When indigo is demonstrable by qualitative tests in considerable amount (at the time of the test) the patient is said to have "indicanuria." Such patients frequently, perhaps usually, exhibit constipation, and it is argued that this leads to excessive putrefaction and formation of indole. Indicanuria is, briefly, commonly believed to be due to derangement of the intestinal functions, and to connote toxæmia of intestinal origin. With regard to urinary indigo in mental diseases, statements have been made from time to time by psychiatrists which indicate a belief that the indigo-producing substances are in excess in recent and acute mental disease, or in exacerbations of chronic insanity, and more especially in manic-depressive insanity and confusional states; according to some, especially in akinetic forms of insanity in general; and this apart from constipation. It has been stated that the urine of sane controls in average and in poor health does not give anything like the indigo-reaction yielded by urine in the above-mentioned kinds and forms of insanity. Certain writers have gone beyond the point of recording an excess of urinary indigo in mental disorders, and claim to have correlated variations in the mental state with variations in the indigo; thus, Taubert,[17] in a case observed by him for six months, believes that he noted a close parallelism between psychic excitement and increased indigo, and states further that the latter was often found 10–12 hours before the maniacal phase. In four cases of manic-depressive insanity he found a considerable and lasting increase of indigo during the maniacal phase, but a fifth case showed none. Pardo[18] also makes a very complete statement as to the direct association of "indoxyluria" with mental states, and speaks of having reduced the elimination of "indoxyl" from a point 10 to 20 times above normal to practically zero by means of what he calls intestinal antiseptic treatment and a milk diet, cure of the mental disorder proceeding *pari passu*. I have never seen beneficial results in insanity from the use of so-called intestinal antiseptics, and it has been shown by Seige[19] that the marked indigo-reaction found in some cases of mania and melancholia is not influenced by measures taken against intestinal putrefaction. Pardo's statements further imply the use of a quantitative method, apparently Maillard's; but the evidence I am about to mention shows that all such methods are unreliable.

Research on Urinary Indigo in Cases of Insanity.

The frequency of a marked positive reaction to the test for indigo in newly received cases of insanity, and in exacerbations in chronic cases, has interested me, in common with others, and some three and a half years since I suggested to my colleague, Dr. Stanford, research chemist at Cardiff Mental Hospital, that he should investigate the subject. The results of Stanford's prolonged and painstaking research have recently appeared in the *Zeitschrift für Physiologische Chemie* (Bände 87 (H. 3) and 88 (H. 1)), a preliminary communication dealing more particularly with the urinary indigo in certain cases of insanity having appeared in the *Journal of Mental Scienec*, April, 1911. Stanford points out that it has been generally assumed that because indigo is produced by the action of hydrochloric acid and an oxidising agent upon potassium-indoxyl sulphate, the indigo-producing substance of human urine is identical with the latter. And since it has been demonstrated in the urine of animals fed with indole, the assumption is further that the indigo-producing substances in human urine are derived from the indole of the intestinal canal. These assumptions are not based upon exact evidence. The indigo-producing substances of human urine have not yet been isolated.

Stanford's examination of more than 2000 specimens of human urine for indigo shows that the indigo-producing substances are extraordinarily unstable, so that the amount present in a specimen is greatly diminished in from 1–3 hours, and in from 3–6 hours from the passage of the urine these substances have mostly completely disappeared. The reason for this is unknown. There can therefore be no question of the exact quantitative estimation of indigo at present, and even qualitative estimations to be of value must be made immediately after the urine is voided. This phenomenon of the disappearance of the indigo-producing substances is not mentioned, I understand, in the voluminous literature upon the subject of urinary indigo. The instability of the substances is scarcely compatible with the assumption that they consist of potassium-indoxyl sulphate, since the chemists who have carefully studied this substance have pointed out its stability under various conditions. It is more probable that they are not always the same, but consist of a mixture of closely-related substances of the indigo group.

An approach to accuracy in the quantitative estimation of urinary indigo is probably afforded by a method briefly described by Stanford, which consists in the colorimetric estimation of a chloroform solution of the indigo contained in each quantity of urine as soon as passed, the coloured solution for comparison being standard Fehling's solution. The formula given by Stanford affords a number which is proportional to the amount of indigo present. By adding together the numbers so calculated for all the samples through the 24 hours a number is obtained which is proportional to the total indigo excreted during that period. In his latest paper Stanford[20] shows that if the extraction of the indigo by chloroform is carried out in an atmosphere of carbon-dioxide a pure blue solution is constantly obtained—a very important advance, as it permits of exact colorimetric comparison. The daily excretion of indigo-producing substances in the urine of a case of mental disease in which the mental state showed no alteration during the 10 days over which the examination was conducted was found by Stanford to vary very considerably, the variation exceeding the limits of experimental error and being unconnected with meals. Whilst recognising, as one must do, from this and other similar observations of Stanford, that there are daily and even hourly fluctuations, it may be still the case that the total indigo found over a given period, by the means now indicated, is greater in certain forms of mental disorder than in sane controls. The researches I have alluded to, which are not concluded, encourage one to believe that comparative quantitative estimations of the substances in question will ere long be available.

Pardo, in the work I have mentioned, argues that the antecedent substance of urinary indigo-red is probably produced by micro-organisms which have migrated from the intestine to the urinary passages, on the basis of experiments in which he inoculated urine, especially alkaline urine, and negative to the indigo-red test, with fæcal micro-organisms. This urine then gave a positive result with the test. But Stanford's researches show that the indigo test is positive in sterile urine. An inquiry conducted by my colleagues—E. Barton White and Stanford—shows that when bacillus coli and bacillus pyocyaneus are grown upon a variety of media of known composition and degree of alkalinity, to which small quantities of indole have been added, no indigo-producing substance was found. Lastly, in respect to the question of urinary indigo, it is to be observed that indigo can sometimes be demonstrated in cases, including cases of insanity, in which there is no evidence of disturbance of intestinal function, so that the indigo-producing substances may not be wholly due to cleavage of proteins in the gastro-intestinal tract, but are conceivably merely the expression of a disorder of metabolism which is associated with mental disorder as cause or effect.

Recently Wladytschko[21] has sought to obtain direct evidence of the noxious influence of intestinal toxins upon the central nervous system by feeding rabbits and guinea-pigs over long periods with parakresol and indole. In these instances he found regressive and destructive changes in the vessels of the brain in the cells (presumably nerve cells), and glial proliferation. The original work I have not had an opportunity to consult. Such direct experiments appear desirable on a larger scale with information as to the degree in which histological changes occur locally and generally.

Bacteriological Examination of Fæces.

One would have thought that the evidence we possess in support of the view that mental disturbance and actual insanity are in some cases due to disorders of the gastro-intestinal tract would have led long since to a critical bacteriological examination of the fæces in these cases. In point of fact, extremely little work has been done upon the subject. In 1911, at the meeting of the British Medical Association at Birmingham, I communicated preliminary results obtained by Dr. E. Barton White and myself as the outcome of the examination of a considerable number of stools from freshly-admitted cases of acute melancholia and acute mania, the first (in a few cases the second) stool passed being taken. This work we carried on, as opportunity occurred, till the close of 1913, the major part of it during the past two years having been done by Dr. White, to whom I would here express my obligations for his coöperation and for valuable assistance in drawing up our results. I would point out that investigations of this kind are extremely laborious, and two workers merely cannot be expected to make more than a very modest contribution to our knowledge. Still, it is absolutely necessary to have even the elementary information we are able to furnish. Apart from our results I know of no work, as far as the insane are concerned, other than that of the Italian workers Pardo and Benigni, which, however, from the bacteriological standpoint is but scanty.

Our procedure in this investigation was as follows: A gramme of fæces was well shaken up in water with sterile shot in a sterile vessel, a suspension of 1 per cent. being thus obtained, from which decimal dilutions were made by transporting 10 c.c. from one vessel to the next, each vessel containing 90 c.c. of water before the addition. Tubes of broth, McConkey's medium, and litmus milk were inoculated from these vessels. The milk tubes were heated a sufficient time at 80° C. to destroy adult organisms, and placed in an anaerobic apparatus in the incubator. Gelatin and agar plates were poured from the higher dilutions, and heated gelatin plates—for the observation of spores—from the lower ones. Agar-fuchsin plates—for the study of colonies—were prepared from the lower dilutions. Examination of the tubes and plates afforded approximate information as to the total number of organisms present; according to the dilution in which they occurred in the former case, and by actual counting in the latter. Anaërobes of the bacillus enteritidis group were studied from the milk tubes. The highest dilution in which typical bacillus coli occurred was ascertained by separating colonies upon a gelatin slope from the higher dilutions of broth cultures, and inoculating upon suitable media, and observing the latter for typical bacillus coli reactions. Subsequently, and only in some cases, agglutination, opsonic, and complement-deviation tests were performed with typical bacilli coli colonies.

Our results are set out in the following tables (Tables V.–IX.), in comparison with the average results obtained by Houston[22] in normal human fæces. From Table V. it appears that 5 out of 10 cases of acute mania showed a larger amount of total organisms (and bacillus coli) than the normal average; of the acute melancholia cases only 4 out of 18 showed the same. But if, as there is ground for believing, the normal upper limit is not more than 100 millions, 9 out of 10 of the acute mania cases, and 10 out of 18 of the acute melancholia cases, are above the average normal figures. As regards streptococci, if 1,000,000 per gramme be regarded as the average, only 3 out of 10 acute mania and 5 out of 18 acute melancholia show higher numbers than the normal. Nearly all the streptococci in the cases examined were of the short-chained variety, in this respect agreeing with the normal. These streptococci, for some unknown reason, only appeared upon agar-fuchsin plate in 4 per cent. of the cases; in the remainder they were obtained direct from the broth-tubes originally inoculated.

The relative number of bacillus coli per gramme in the specimens examined is set out in Table VI. Whereas in the normal cases no less than 82 per cent. of the specimens showed no more than 10 million, no less than 90 per cent. of the acute mania and 55 per cent. of the acute melancholia cases showed more than 10 million. Table VII. shows the frequency of anaërobic organisms giving the

cultural, morphological, and staining reactions of bacillus enteritidis. In 8 out of 10 cases of mania and 13 out of 18 of melancholia the numbers estimated as present were below the average normal numbers. Table VIII. shows that aërobic spores were absent or in greatly reduced numbers, in both these forms of insanity. Table IX. shows that the bacillus coli present in both forms were typical in as high a percentage of cases as obtains for normal stools. The apparent exception furnished by the reaction of fluorescence in the cases of depression may with some likelihood be attributable to certain instances of faultily prepared media. The agar-fuchsin plates did not show other than the usual colonies present in normal stools. The bacillus coli found were usually acid-forming, only about 6 per cent. giving no red colouration. Typical bacillus coli (the cases were of mania or melancholia) were submitted to agglutination and opsonic index tests. The results in respect to agglutination were unlike those obtained in normal persons by Houston (a certain proportion giving a positive result) in that agglutination failed to occur, and with a low degree of dilution of the serum, in any case; but at any rate they resemble his in the point that the results in the controls were the same (in each case the organism used was the patient's). As regards the opsonic index ("homologous"), this was higher than the control-observation in seven instances, lower in four. Lastly, it is interesting to note that complement-deviation did not occur in these cases, either when the patient's serum or that of a control was used.

One may summarise such information as this small contribution to the subject of the bacteriology of the fæces in acute mania and melancholia affords thus: an increase was found in the total number of organisms and of bacillus coli in the great majority of the cases of mania, and in rather more than half the cases of melancholia; a diminution in the anaërobic organisms investigated in the great majority of the mania and the majority of the melancholia cases; a considerable diminution (or absence) of aërobic spores in both kinds; an absence of atypical bacillus coli and of unusual organisms in both kinds. Lastly, these cases afford no evidence that bacilli coli, even though present in abnormal quantity, exercise any influence in the conditions dealt with.

Johnson and I[23] examined the agglutinating power (upon bacillus coli) of the serum in dilutions of 1:100 (90 cases), 1:50 (3 cases), and 1:30 (7 cases) in 100 cases of insanity, of which 29 were cases of acute melancholia, 53 of acute mania, 9 of delusional insanity, 6 of general paralysis, 2 of alcoholic insanity, and 1 was a case of acute dementia. Of the 100, 50 showed agglutination described as "good" or "partial," though as many as 39 of them gave only "partial," and 50 showed no agglutination. Controls showed no agglutination in 84·6 per cent., the rest of the cases showing, with one exception, only partial agglutination. To present this observation concisely, 89 per cent. of the insane cases (the bulk of them composed of cases of melancholia and mania) gave either only partial agglutination or none at all. The organisms were foreign ones, and not the patient's own; single strains in 75 per cent., mixed strains in 25 per cent. These observations agree with those of White and myself in showing that in acute and recent insanity there are, in the rule, no agglutinins formed against bacillus coli.

In the following cases I examined the stools with a view to ascertaining whether there was a preponderance of Gram-positive organisms, the cases being all acute and recent, newly admitted. An emulsion was made in sterile distilled water of a portion the size of half a marble from the centre of the stool, 8–10 c.c. of this was centrifugalised for 10 minutes; one part of the supernatant turbid fluid was mixed with two parts of a 96 per cent. solution of alcohol, and the mixture centrifugalised for half an hour. The deposit, which consisted practically entirely of bacteria, was stained on cover-slips by Gram and counter-stained with carbol-fuchsin. Table X. gives the results:—

TABLE X.—*Showing the Number of Gram-positive Organisms in Fæces.*

D. L.	Adult, healthy working imbecile (as control).	—	Fuchsin-stained, but Gram + fair sprinkling.

Having regard to these results I was surprised to find that Pardo records the preponderance of Gram-fast organisms in cases of mania and melancholia in stools. He gives two plates, one showing the bacteria of the stool at the beginning, the other at the close of a maniacal attack; in the former violet-stained organisms preponderate, in the latter red-stained. His suggestion is that the flora in these cases is that of protein-putrefaction, and that the proteolytic anaerobes—which are Gram-fast—are present in excess at the outset of the attack. The observations recorded above lend no support to Pardo's views, and the results recorded by Barton White and myself fail to afford evidence in favour of Pardo's statement that the putrefactive anaerobes are increased at the expense of bacillus coli and B. aërogenes, the normally-preponderating organisms; nor do they support his statement that streptococci are increased. In future work on the intestinal flora in acute and recent cases of insanity it seems to me particularly desirable that the anaërobes should be studied, as these are the organisms about which we know least in these conditions, for the sufficient reason that they are the most difficult to work with.

Anaërobic Organisms: Agglutination Test and Opsonic Index.

The chief obligatory anaërobes of the human intestine are commonly stated to be bacillus putrificus, bacillus aërogenes capsulatus (bacillus Welchii), and bacillus enteritidis sporogenes (Klein). In conjunction with Dr. Schölberg I carried out an investigation with a view to ascertaining the results of the agglutination test and to estimating the opsonic index, in respect to two of these anaërobes, bacillus putrificus and bacillus enteritidis sporogenes, in recent and newly-admitted cases of acute mania and acute melancholia. We worked with stock cultures of these organisms. Repeated efforts to obtain a pure culture from various sources of bacillus aërogenes capsulatus failed. Even in respect to the other two anaërobes the difficulties surrounding this work were considerable, for it was necessary to maintain them for a very long time in pure culture pending the admission of suitable cases of the forms of insanity (mania and melancholia) we investigated. Our results are here summarised. The agglutination test was done in the low dilution of 1 in 20. The opsonic index was estimated for each of the two organisms thus:—

I.	II.	III.
Control's serum	Patient's serum	Patient's serum.
,, leucocytes ...	,, leucocytes...	Control's leucocytes
Organism	Organism	Organism.

In none of the 22 and 25 cases respectively in which the agglutination test was carried out was there a positive result, and when a partial reaction was recorded it was shown by the control as well as by the patient and in equal amount. The opsonic index was estimated upon admission of the patient 18 times in the case of bacillus enteritidis; in 12 it was less, in 6 more than in the control. It was estimated on 22 occasions in the case of bacillus putrificus; in 15 it was less, in 5 more than in the control, in 2 the same. These results point in the same direction as those referred to below (respecting the opsonic index in the case of various common organisms), and merely indicate a lowered resistance in the majority of the patients. In addition to the usual control an observation was made in the above cases with a mixture designated above as No. III., in which the patient's leucocyte was replaced by the control's leucocyte, so that the mixture was heterologous. It is interesting to note that 15 times out of 19 in the case of bacillus enteritidis, and 16 times out of 22 in that of bacillus putrificus, the opsonic index was higher with the heterologous than the homologous mixture. Without indulging in speculation as to the relative rôle of the serum and the leucocytes in the process of ingestion of organisms by the latter, this observation would appear to indicate that the part played by the white cells is of greater importance than they are usually credited with. The observation has interested me considerably, as affording a possible basis for the treatment of toxic conditions by the injection of foreign leucocytes, a matter to which I refer in my next lecture.

Observations upon the opsonic index in respect of various common organisms in cases of insanity have been recorded by Shaw[24] and by Babington,[25] the former examining 15, the latter 52, cases of various kinds. The organisms tested were bacillus coli, staph. aureus, streptococcus fæcalis, bacillus paratyphi, microc. rheumaticus, and bacillus tuberculosis. Both these observers found that the index was on the average lower in the acute insane than in normal, healthy controls, and the former observed that the index varied more in the insane. The index was found by Babington to be lower especially with bacillus coli; and to rise to normal, or higher, in respect to the organisms as a whole, after recovery. These observations go to show that the insane, especially those suffering from acute forms of insanity, are more liable to infection than healthy normal persons. No doubt this was *a priori* probable, but evidence is, of course, necessary in such matters.

LEUCOCYTOSIS IN MENTAL DISORDERS.

The demonstration of leucocytosis in toxic conditions led in due course to the study of the white blood corpuscles in the psychoses, especially in those which *a priori* might be associated with such conditions. As regards the erythrocytes, all workers are agreed that, in respect to them, and to the amount of hæmoglobin present, there is nothing of special significance to record in the insanities; the numbers of the former and the percentage of the latter are merely reduced in proportion to the reduction in general health. In regard to the leucocytes in mental disorders, a considerable amount has been written and important deductions have been made. I first allude to those records which in my judgment are noteworthy, and subsequently to certain personal observations, and finally summarise.

Dementia Præcox.

The largest number of observations seems to have been made in respect of the mental states grouped under the heading of dementia præcox. Sandri,[26] an Italian observer, studied 32 typical cases, acute and recent, and 8 chronic cases, of many years' standing. The former he was fortunate enough to be able to examine in from ten days to three months from the commencement of the disease. In acute instances of the hebephrenic and paranoidal forms he found a moderate leucocytosis—up to about 10,800—and a slight increase in the neutrophiles at the expense of the lymphocytes. In acute cases of the katatonic form—to my mind the most striking of the varieties—Sandri found no leucocytosis, but a relative increase of the lymphocytes, especially the small kind, at the expense of the neutrophiles. These conditions, it will be remarked, are the exact reverse of those obtaining in the other two varieties of dementia præcox. Further, in the katatonic type the cell protoplasm and the nucleus showed various signs of degeneration, and myelocytes were numerous; in the other two forms the cells and their nuclei were commonly well preserved. Amongst the eight chronic cases only those of the katatonic type showed changes of the same kind as in the acute cases. These observations, therefore, purport to draw a marked distinction between the katatonic and the other types. Graziani[27] does not find any distinction in the leucocytal counts in the three types of dementia præcox. Confirming the observations of Bruce and Peebles, which were in respect of the katatonic type, he describes a moderate leucocytosis with increase of the neutrophile percentage at the beginning of the malady. In such incomplete recovery as one finds in these cases, he agrees with the authors mentioned, that the neutrophile cells are maintained at a fair percentage (60 per cent.). With the supervention of dementia the total count and the proportion of neutrophiles both diminish, with proportional increase of the lymphocytes; with this statement other writers, such as Dide and Berkley, agree. Camus and Lhermitte[28] find a very moderate leucocytosis—up to 10,000 only—in dementia præcox, persistent throughout the malady, with a proportionate increase of lymphocytes. Heilemann,[29] coming to recent writers, is clear that there is a change in the cell-count in dementia præcox, although the observations of the various writers are, as he truly remarks, difficult to coordinate and interpret. They seem, on the whole, to agree that there is a lymphocytosis—not limited to katatonia, as Sandri states. In a table of 24 cases Heilemann shows that neutrophiles are low and lymphocytes and eosinophiles increased. He is unable to say whether there are differences in different forms of dementia præcox. Pförtner[30] (1912) finds a moderate leucocytosis with relative lymphocytosis, so that lymphocytes amount to 58–59 per cent., whilst neutrophiles are notably diminished. He finds no differences in the counts in different forms of the malady. He describes hypo-eosinophilia in 43 per cent. Acute exacerbation was accompanied by hyper-leucocytosis, with relative neutrophile increase, in two cases, which conditions subsided with the exacerbation—a picture very suggestive of the influence of a toxin. But very often important changes occurred in the relative proportion of the varieties of white cells without change in the clinical picture and *vice versâ*. Barnes[31] reports two similar cases to the above. A very important communication upon the blood-changes in dementia præcox appeared in 1912 by Lundvall,[32] based upon the systematic study of 15 cases covering the different phases of the disease in the same patient, observations being made daily, or every second day, for a long period. He finds that there are typical blood-changes, which he terms "blood crises," at periods marked by psychical and motor unrest. These consist in oligocythæmia and hyperleucocytosis, characterised by increase in the neutrophiles. These crises appear earlier than the psychical changes. In the intervals there is a diminished total count with relative mononuclear increase. Lundvall's observations, taken with those of the last two writers, seem to me of particular importance as indicating a destruction of red blood corpuscles and a positive chemiotaxis—conditions which point to a bacterial invasion rather than to an endogenous toxæmia. Unfortunately, one rarely sees a case of dementia præcox in a mental hospital in the initial phase. In consulting practice, I am informed, such cases can be watched developing for very many months, but I can well understand that it is well-nigh impossible in such practice to make blood-examinations systematically and in connexion with exacerbations.

Summarising our present knowledge, it may be stated that in the earlier phases of dementia præcox there is a moderate increase in the total white cell count, with relative increase of the neutrophiles. Thereafter in marked exacerbations of the morbid processes these increases are more pronounced. The ordinary picture is that of a relative lymphocytosis. The progress towards dementia is characterised by a persistence of this, with a low total count; this appears to be the view held, but I would refer to a chart which follows as to this point. There is no sufficient evidence of differences—quantitative or qualitative—in the cell-counts in the different forms of dementia præcox, though in quite a recent communication Kulm and Purdum[33] confirm Sandri's statement as to the high proportion of lymphocytes in the katatonic variety. The need of more extensive observations, for comparative observations in respect of the different forms, for observations in the very early stages of the morbid process, is, I believe, greater in the disorders grouped under this heading than in other kinds of insanity. The physical condition of many cases of stupor and katatonia bears a resemblance to that found in myxœdema, in which disease there is also a relative lymphocytosis.

Insanity with Epilepsy.

Graziani finds what he describes as the characteristic formula of the toxic-infective state—viz., leucocytosis and polynucleosis, with hypo-eosinophilia at the time of seizures; the statement is not complete. Morselli and Pastore,[34] and also Campioni,[35] who paid attention solely to the eosinophiles, agree that there is a hypo-eosinophilia for a few days prior to the attack, which persists during it, the eosinophile ratio rising after it—conditions pointing to negative and positive chemictaxis, according as toxin is present in quantity or is diminishing. These statements of the Italian observers, in respect to leucocytosis, polynucleosis, and eosinophilia, in relationship to the phases of the epileptic condition, are entirely borne out by the French observers Klippel and Feil[36] (leucocytosis, 20,000–22,000). The subsidence of leucocytosis and the rise in eosinophiles are comparable to what is seen in convalescence from acute infections. Nieuwenhuize[37] and Jödicke[38] find that there is usually no leucocytosis before a seizure, but the latter describes two cases in which there was a marked rise in the number of white cells a few days before such. Riebes[39] found in seven cases examined immediately before the seizure a polynuclear increase of 15 per cent. to 20 per cent., with corresponding diminution of lymphocytes. Between seizures he obtained discordant results. As to eosinophiles, he agrees with the authors cited. Bruce[40] found hyperleucocytosis during all stages, but most marked during and after seizures. Gorrieri[41] describes a more or less pronounced leucocytosis during and after seizures, in some instances evident a few minutes before the seizure; in the intervals the count is in general higher than normal, but considerable individual differences obtain. The summary seems justified, in respect to epilepsy with insanity, that there is a considerable degree of accord between observers, the results showing leucocytosis with hypo-eosinophilia in connexion with seizures, uncharacteristic conditions obtaining in the intervals; in other words, evidence of toxæmia, not acute, at the time of the seizures.

More observations are needed, especially during the premonitory period.

Mania—Melancholia.

Graziani finds a leucocytosis of moderate degree (12,000–16,000), with polynucleosis, at the commencement of the attack, and the like on relapse. The neutrophile count remains high in cases which last for months without improvement. At the close of the attack of ordinary duration the neutrophile count is low. A rise in the eosinophile count is of good omen; experience supports this, which is *a priori* probable. Bruce describes a high total count, with relative neutrophile increase, at the onset; these subside as the disease progresses, and perhaps a second minor increase accompanies symptoms of recovery. The persistence of this, with a normal percentage of neutrophiles, after recovery is a favourable sign. A fall in the neutrophile percentage without mental improvement is, as McDowall[42] has pointed out, an unfavourable sign. In unfavourable cases the leucocytal counts are variable, and lymphocytosis becomes apparent with the lapse of time. In subacute and chronic conditions lymphocytes predominate (Klippel and Léfas[43]).

To summarise, there is general agreement as to a leucocytosis at the beginning of an attack of acute mania or acute melancholia, and with increase of the neutrophiles; and the few who have studied the leucocytal count throughout the normal course of a favourable case would not dispute the accuracy of Bruce's statement concerning it. More evidence is required as to subacute and long-lasting cases, and as to the count at the stage when it is apparent that recovery is to take place. Whilst statements as to isolated occasional white cell counts in acute mania and melancholia are pretty frequent, it is remarkable how few have conducted inquiry in these conditions over long periods. This criticism applies to the cell-counts in the psychoses generally, but one would have thought an exception would have been made in cases of the particular kind just discussed, conveying strongly, as they do, the impression of toxic pathogenesis.

In puerperal insanity the leucocytal counts resemble those of acute mania. A record by Gorrieri[44] of the white cell count in cases of acute alcoholic insanity, recovering within three months, is interesting, because it is rare, and because it bears out the association of a polynuclear increase, accompanied by relative diminution of lpmphocytes, with a toxic process. The qualitative count became normal upon recovery, with rise in the proportion of eosinophiles.

States of Acute Confusion ("Amentia" of the Italians).

Graziani and Sandri agree in the main. There are the usual conditions which go with what appears clinically to be a toxic state—viz., leucocytosis (slight), polynuclear increase (not marked), hypo-eosinophilia. These pass away with decline of the illness and recovery. The case of mental disorder due to pellagra is of great interest from the comparative standpoint, when regard is had to the outcome of modern investigations as to its pathogenesis. Bardin,[45] in 14 uncomplicated cases, found lymphocytosis (affecting the small lymphocytes especially), with diminution of the polymorphs, this condition being especially marked in the chronic cases.

Dementia Paralytica.

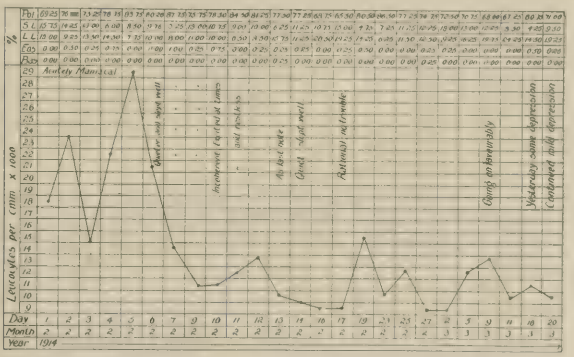
My experience is in accord with that of Klippel and Léfas, and Bruce and Peebles; in the first stage there is a moderate leucocytosis with relative neutrophile increase (75 per cent. to 80 per cent.); in the early second stage these conditions continue, but in the later second and in the third stages, whilst the moderate leucocytosis (up to about 11,000 cells per c.mm.) is maintained, the lymphocytes, small and large, are relatively increased at the expense of the neutrophiles, which fall to from 54 per cent. to 64 per cent. A relative polynucleosis, with frequently only slight increase in the total count, accompanies the febrile attacks of the later stages, and also the paralytic seizures. The illustration of this point and that of the leucocytal count in states of remission (which I have studied over long periods), and a final summary of the subject under notice, I must defer to my third lecture.

Charts Illustrative of Leucocyte Count.

I conclude this lecture by submitting the following few charts illustrative of the leucocytal count in certain recognised kinds of insanity. The number representing the total leucocytes is in each case the average of three total counts of 400 squares each. The percentages of the different kinds of leucocytes are based in each case on 400 consecutive leucocytes.

CASE 1A (Fig. 1).—Patient aged 27 years. Puerperal mania. Duration of disease on admission, one week. Observations (25) over a period of 1¾ months. Hyperleucocytosis during period of acute mania, with sudden fall on its cessation. Moderate increase in total count thereafter. Hypo-eosinophilia throughout. (Patient not completely recovered on cessation of observations, but quite free from mania.) The high neutrophile percentage practically throughout is obvious, and indicative of a toxic process.

FIG. 1.



Puerperal mania. Case 1A. admitted Jan. 31st, 1914.
The reduction necessitated by the size of some of the original drawings has made the lettering in some places difficult to follow, a remark which holds good for other of these charts. Under a low magnifying glass the figures are plain.

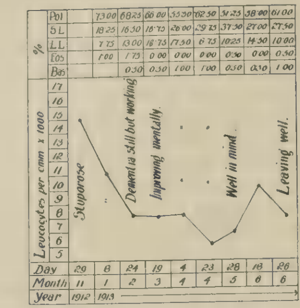
CASE 3 (Fig. 3).—Patient aged 21 years. Confusional insanity. Duration on admission, two weeks. Leucocytosis at outset, disappearing with cessation of the disorder. Polynuclear percentage well maintained at outset, but relative lymphocytosis towards and at close. Eosinophiles very low throughout.

CASE 4.—Patient aged 49 years. Subacute melancholia; agitation and confusion. Duration on admission, some months. Prone to relapse; previous attacks. Observations (27) over one year and two months. This is the case of a woman in mental hospitals three times and for a total period of nearly six years during the past seven years, so that she has remained comparatively well for a very brief period only during seven years. There is a variable total leucocytal count without correlation with clinical manifestations. No marked leucocytosis except when the condition at its worst—

on reception. A relative lymphocytosis is the feature of the qualitative count. A low eosinophile count. The chart of incomplete recovery. (Fig. 4.)

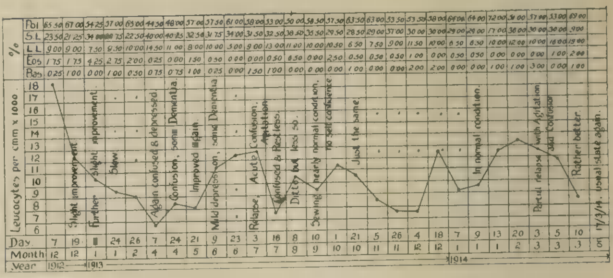
CASE 5.—Patient aged 50 years. Acute melancholia on admission, thereafter chiefly subacute. Duration on admission some months. Observations (23) over nearly one year. Total count shows instability, with leucocytosis in latter half of observation-period, in conformity with the unsettled and relapsing clinical condition. Mostly a relative lymphocytosis; rarely a normal proportion of polynuclears, not maintained. Hypo-eosinophilia. Unfavourable prognosis for complete recovery. (Fig. 5.)

FIG. 3.



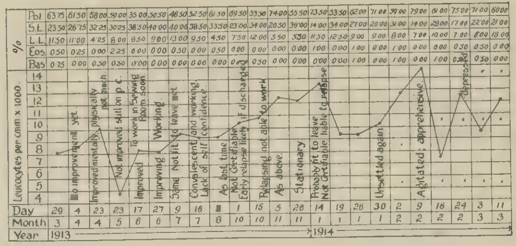
Confusional condition. Case 3, admitted Nov. 27th, 1912. (A certain number of the charts not appearing in this issue of the lectures, the numbering is not consecutive.)

FIG. 4.



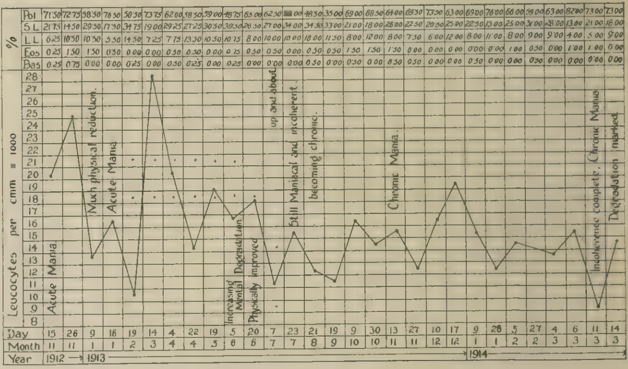
Subacute melancholia. Case 4, admitted Dec. 5th, 1912.

FIG. 5.



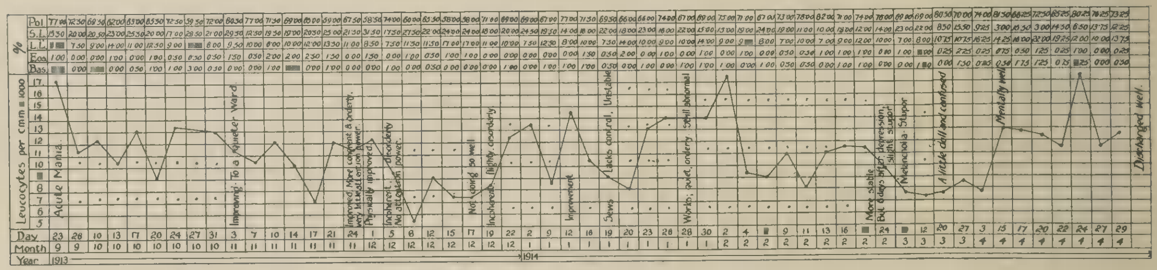
Acute melancholia. Case 5, admitted March 3rd, 1913.

FIG. 7.



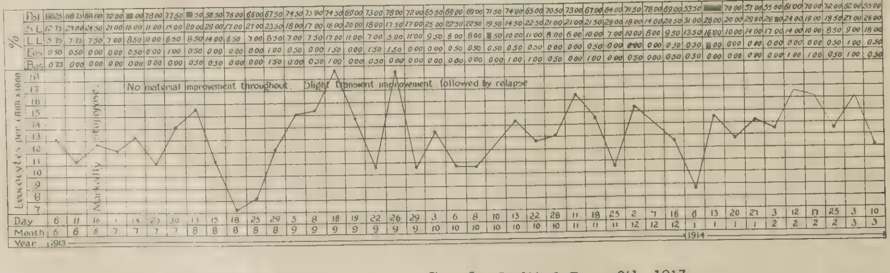
Acute mania. Case 7, admitted Nov. 11th, 1912.

FIG. 8.



Typical acute mania. Case 8, admitted Sept. 9th, 1913.

FIG. 9.



Dementia præcox; stupor. Case 9, admitted June 6th, 1913.

CASE 7.—Patient aged 45 years. Mania, first acute, later chronic. Duration on admission two to three weeks. Observations (28) over a period of 1 year 4 months. Marked leucocytosis on two occasions, early, otherwise moderate, with much variation of total count. Towards close, diminishing total count, but no fall in polynuclear percentage. Deficient polynuclear reaction frequent in course of the case (unfavourable sign). Eosinophile count very low or absent. (Fig. 7.)

CASE 8.—Patient aged 19 years. Acute mania. Duration on admission, one month. Observations (55) over a period of seven months. Marked irregularity of total count, with mainly a moderate leucocytosis. Polynuclear percentage mostly well maintained, and consistently so when nearing recovery. Low eosinophile count. (Fig. 8.)

CASE 9.—Patient aged 23 years. Dementia præcox (stupor). Duration before admission, two months. Observations (40) over period of nine months, moderate leucocytosis throughout; irregular count. Polynuclear percentage well maintained or increased during first half of the period, but in second half a drop in the polynuclear percentage is frequent, especially as case progresses. Very low eosinophile counts throughout. (Fig. 9.)

Observations in 6 cases of epileptic insanity—30 pre- and 39 inter-paroxysmal.—Doubtless it is desirable to make numerous and regular observations in the same patient, but the frequency with which fits occur in cases available for observation is often not sufficient to allow of the collection of results within the time at disposal. Taking the series of observations made in these six patients I find that of the 13 highest counts 11 are preparoxysmal; and of the 15 lowest, 12 are interparoxysmal. A moderate leucocytosis is, on the whole, the prevailing condition throughout. No correlation is to be made out between varieties of cell and phases of the disease. Eosinophiles are low.

The hypo-eosinophilia noticeable in all these charts, illustrating different kinds of insanity, is noteworthy.

Observations on three typical cases of the chronic phase of dementia præcox in adolescents free from other disease.—All were of a few years' standing. Twenty-seven observations in all. The total count can only be called normal on five or six occasions; otherwise a leucocytosis (or a lymphocytosis) with considerable variations, no clinical change accompanying them. The neutrophile percentage is below the normal figure on 14 out of 27 occasions, there being an increase in the percentage of lymphocytes (the large mononuclears chiefly). In five instances the eosinophile percentage is increased, and in six the basophile percentage is at the upper normal limit. These observations are perhaps of interest because records in the chronic cases of dementia præcox are rare.

NOTE ON THE WOUNDS OF THE SOFT PARTS PRODUCED BY THE MODERN BULLET.

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,
COLONEL, ARMY MEDICAL SERVICE; CONSULTING SURGEON TO THE EXPEDITIONARY FORCE.

THE time seems to have arrived when an opinion may reasonably be expressed as to the so-called "humane" character of the pointed bullets employed in the present war. Before proceeding to this consideration the protest may be reiterated against the "pure sentiment" which has given rise to the employment of the word "humane" and led to international recrimination between parties who, while advocating the employment of a "humane bullet," do not hesitate to place their main hopes on the use of projectiles portions of which may cut off a head, an arm, or a leg, or lay open the major part of one or more of the great body cavities.

Characters of the Wounds.

The main characteristics of the wound produced by the modern pointed bullet depend on two factors—initial velocity of flight and instability of flight in the long axis of the projectile. Of these two factors the former is of comparatively small importance except in the increased capacity of the bullet to produce extensive comminution of the bones when they are struck at a right angle. In the instability of flight and the tendency of the bullet to revolve around a transverse axis, however, the travelling bullet is endowed with a capacity of wounding the soft parts to a degree which no form of expanding or soft-nosed bullet has exhibited before. A dum-dum or a soft-nosed bullet traversing the soft parts alone seldom acquires any deformation or increased wounding power, and, as far as my own experience of the dangers of the soft-nosed Mauser or Mannlicher bullet occasionally used by the Boers in the South African campaign went, I came to the conclusion that they were practically negligible.

On reviewing a long series of the bullet wounds observed during the last two months of the present campaign I have become more and more impressed with the gravity of a considerable proportion of the rifle and machine-gun wounds, which seems to me to correspond much more nearly with the experimental results obtained by von Fessler and others than with the reports furnished by many of the surgeons working during the Balkan campaign, the majority of whom regarded the wounding power of the pointed bullet to be very similar to that of the older dome or ogival tipped bullets of small calibre. That the pointed bullet causes small, clean apertures of entry and exit when it strikes fairly at right angles, even when travelling at high degrees of velocity, there is no doubt. Such wounds are numerous, although in my experience the cases in which occurs perforation or division of small narrow structures such as the peripheral nerves and arteries are not so common as was the case in wounds produced by the Mauser or Lee-Metford bullet.[1] Neither arterial hæmatomata nor aneurysmal varices have been frequently seen in the more serious cases reserved for treatment in France, although I am not in a position to know what may have been observed amongst the large number of less severe wounds transferred at once to England. The same remark applies to isolated injuries of individual peripheral nerves, while the larger area afforded by the brachial plexus has resulted in many paralysed arms complicating the very common wound from the base of the neck to the shoulder region, the result of the attitude so often assumed in the fighting during this campaign.

---

[1] THE LANCET, Dec. 20th, 1913, p. 1743.

Allowing the capacity of the pointed bullet to produce the small apertures of entry and exit and the narrow intervening canal made by the older bullet, yet it is clear that as a cleanly perforating instrument it needs to strike with extreme accuracy and precision, and if this be not the case wounds of a vastly different character result. A slight inaccuracy of impact causing only an unimportant increase (or none at all) of the aperture of entry, may result in the production of an "explosive" exit aperture of the extreme type when no bone has been touched and the resistance of the soft parts of the body is alone met with.

Instability of Flight of the Pointed Bullet.

That these wounds are not caused by bullets deformed by ricochet is obvious from the characters of the aperture of entry. On this point it may be added that seriously deformed bullets are seldom extracted, which may depend on the fact that in the recent fighting a large number of the deflected bullets have struck either trees or the soft earth at the margin of the trenches. The more serious ricochets, those from the walls of houses, have been far less abundant. Again, in any case the general outline of the bullet renders it more liable to deflection than to serious deformation unless it meets the opposing object at a very narrow angle.

The ease with which the pointed bullet may be deflected cannot be more aptly illustrated than by examining a number of cases of injury to the head and observing the very great preponderance of gutter wounds over that of tracks traversing the skull, which preponderance (if it existed) was certainly far smaller with the older forms of bullet of small calibre.

The serious nature of the wounds limited to the soft parts can only be attributed to the fact that the instability of flight of the bullet in its long axis is so great that, unless impact with the body takes place by almost the exact tip, a rapid revolution of the bullet on its transverse axis occurs, so that the only slightly diminished force is exerted by the whole lateral area of the bullet on the tissues in the distal portion of the canal and the aperture of exit. If the "remaining velocity" is great this half turn only is probably made; if less the revolution may be complete or even repeated; if the bullet is nearly "spent" it is often retained in a reversed position. The latter is often the case with retained bullets, or their position may be vertical to the course of the wound. The soldiers assert that the enemy sometimes draw out the bullet and reverse its position before firing the cartridge, but even if this be the case it is difficult to believe either that the bullet would travel properly, or that it could account for the many cases of reversed retained bullets met with.

Illustrative Examples.

Evidence of this instability of flight is offered by the appearance of some of the entry wounds; thus rarely wounds are seen of the same outline as the lateral surface of the bullet. On the other hand, the oval wound or the partial gutter leading to a penetrating wound often observed in the case of oblique impact in the case of the older bullets is rare and never well marked. The aperture of entry is rather only slightly enlarged, with merely slight bevelling in one half of its circumference and undercutting at the other. The aperture of exit, on the other hand, is very large, in the case of wounds of the soft parts often oval, and less commonly stellate than when the bones have been implicated. In place of a small tag of subcutaneous tissue in the opening a mass of the brush-like ends of torn muscle and other soft tissues protrudes. Such wounds are seen in the extremities without any evidence of implication of the bones. Very striking instances are seen in the abdomen, thus, (1) a normal small entry wound in the right loin, with a vertically oval wound of the anterior abdominal wall four inches in length, the floor of which was formed by the ascending colon, from which fæces were escaping; (2) a normal entry wound over the ascending colon with an oval exit in the right loin, 3 inches by 2, from which urine escaped and extravasated under the skin of the back; (3) a similar wound entering over the descending colon, with exit in the left loin (in this instance the main urinary extravasation followed the line of the ureter into the pelvis); and (4) entry in the anterior abdominal wall, exit in the left loin, with protrusion of a piece of omentum 6 inches long.

Wounds implicating the thorax scarcely come into the same category, since the presence of a rib at the distal end of the track offers a bony resistance, yet the large valvular openings allowing the free exit of blood and ingress of air which are so often seen were certainly rare in the case of the older bullets.

The chief novelty of the last weeks has been the arrival of men wounded by the modern "hand grenade," which, however, appears to cause more damage to the trench than its occupants.

NOTE ON A FATAL AND EXCEPTIONALLY INTENSE INFECTION WITH MALARIA (P. FALCIPARUM).

BY J. W. SCOTT MACFIE, M.A. CANTAB., M.B. EDIN.,
WEST AFRICAN MEDICAL STAFF.

THE case of malarial fever, a few notes on which are given below, occurred at Sekondi, an important seaport of the Gold Coast Colony, West Africa, and the terminus of the railway which runs northwards into Ashanti as far as Coomassie. Mosquitoes are said to be very troublesome at Sekondi. Simpson (1914)[1] records that on his visit he caught Culex invidiosus, C. rima, Ochlerotatus domesticus, and O. irritans; and states that Stegomyia fasciata was by no means uncommon. His list is not, of course, exclusive, and no doubt other species also occur. The history of the case was similar to that which so often precedes an attack of blackwater fever, and included the following factors: an exacting life, bad quarters, exposure to mosquito bites, repeated attacks of malarial fever, and negligence in the taking of quinine as a prophylactic. I am indebted to Dr. E. W. Graham, senior medical officer, West African Medical Staff, in whose practice the case occurred, for the following notes.

The patient, who was 38 years of age, was employed as a driver on the railway between Sekondi and Dunkwa, and was accustomed to sleep alternate nights at these two places. At the time of his last illness he was in the fourth month of his first tour in West Africa, but he had previously been for five years in India. His quarters in Sekondi were insanitary and infested by mosquitoes, and he stated that he had neglected to take quinine as a prophylactic for some time previous to his admission. On July 15th, 1914, he was admitted to the Sekondi hospital suffering from subtertian malaria. The infection was a slight one, and he was discharged five days later. On August 3rd he was readmitted. On this occasion he was slightly delirious, and his blood showed a heavy infection with quartan and subtertian malaria parasites. As the result of intramuscular injections of quinine he made a good recovery, and was discharged on August 10th with instructions to continue taking quinine, a precaution which, unfortunately, he failed to carry out.

His last illness commenced on August 30th. At mid-day, when he was first seen, he was slightly jaundiced, and looked very ill. His temperature was 103° F., and his pulse 120. He had profuse vomiting. On admission to hospital, at about 2 o'clock, his temperature was 101°. The blood films referred to below were taken at this time. The next morning, at 6 o'clock his temperature was 97·6°, pulse 84, and he looked much better. His urine was normal, his heart sounds a little hesitating, his liver normal, and his spleen only very slightly enlarged. His temperature began to rise again at 2 P.M., and reached its highest point, 104°, at 5 P.M. The patient, however, became comatose, and in spite of every effort died at 6.50 A.M. on Sept. 1st.

Two blood films, the one a thick dehæmoglobinised film and the other a thin film, were kindly sent to the laboratory at Accra by Dr. Graham. The films had been made from the patient's blood on August 30th at 2 P.M., at a time when his temperature was 101°. On examination the thick film was found to consist of a compact mass of malaria parasites. In the thin film, at first glance, as Dr. Graham himself wrote, "two out of every three red blood corpuscles appeared to be infected, in many cases with two or three parasites." One or two segmenting forms of Plasmodium malariæ were found in the film, but with these exceptions practically all the parasites were young ring forms of Plasmodium falciparum. They varied in size from minute bodies with almost solid protoplasm to well-developed rings with a large central vacuole, and not infrequently two widely separated chromatin dots. Very many of the parasites were situated at the extreme periphery of the corpuscles, their chromatin masses projecting out beyond the margin of the cells, and their cytoplasm forming small arcs of the circumferences. It was impossible to determine whether these parasities were really intracellular or not. The appearance of the film certainly suggested that there might be as many parasites present as erythrocytes; but naturally enough, on more careful examination, this was found to be an over-estimate. 2000 red corpuscles, taken as they came, were counted, and the presence or absence of parasites in each noted. The result is given in Table I. Parasites were present in 47·65 per cent. of the red corpuscles; a single parasite in 29·7 per cent., 2 parasites in 13·55 per cent., 3 in 3·5 per cent., and 4 in 0·7 per cent. Three of the 2000 red corpuscles contained 5 parasites apiece, and 1 contained 6. There were therefore 1423 parasites in the 2000 red corpuscles counted.

TABLE I.—*The Distribution of 2000 Red Corpuscles according to the Number of Parasites Invading them.*

—	Number of red corpuscles counted.	Percentage.	Total number of parasites in the red cells of each class.
Uninfected	1047	52·35	0
With 1 parasite ...	594	29·70	594
,, 2 parasites ...	271	13·55	542
,, 3 ,, ...	70	3·50	210
,, 4 ,, ...	14	0·70	56
,, 5 ,, ...	3	0·15	15
,, 6 ,, ...	1	0·05	6
Totals	2000	100·00	1423

In his "Prevention of Malaria," under the heading "The Maximum Number of Parasites," Ross (1910)[2] states: "In Mauritius we found in a fatal case 12/100 of the hæmatids infected." Several authors record 30/100, and Rogers (1908, p. 222)[3] mentions a fatal case "with more parasites than corpuscles"; and Deeks and James (1911)[4] recorded a case, No. 204 of their series, in which "almost every corpuscle appeared to be infected" with tertian parasites. The present case is therefore one of exceptional severity, and if for no other reason would perhaps be of interest on this account. There were, however, other points in connexion with it of equal or greater importance.

It is, I believe, very rarely that unquestionably free parasites have been described in the peripheral blood in malaria. Forms "applied" to the corpuscles are not uncommon, but parasites actually separated from the cells are rare. In this case, however, in addition to the 700 odd intracellular parasites per 1000 red corpuscles, a considerable number of extracellular ones were found also. As they were not evenly distributed over the film, and as a good many parasites were found lying on the extreme margins of the corpuscles about which it was impossible to decide whether they were really intracellular or merely attached to the surface of the corpuscles, it was impossible to determine their percentage accurately. Many of them appeared in the stained film as merozoite-like bodies, and possibly they were merozoites which, in consequence of the intensity of the infection, had not succeeded in penetrating corpuscles. Others were definitely ring-shaped, and like the intracellular parasites not infrequently possessed two chromatin masses. As parasites were also found which appeared to be half inside and half outside corpuscles, it is possible that these free forms had either escaped from, or been squeezed out of, the corpuscles. A natural corollary to the occurrence of these free forms in the plasma was perhaps the fact that polymorphonuclear leucocytes were relatively numerous, and were found to have ingested large numbers of parasites.

A differential count, based on the enumeration of 1000 leucocytes, showed that 58 per cent. were polymorphonuclear cells, 31·5 per cent. large mononuclear or transitional cells, and only 10·1 per cent. lymphocytes. (See Table II.) The low percentage of lymphocytes is probably to be accounted for by the unusual degree of polymorphonuclear leucocytosis, and this, as I have suggested above, may have been evoked in an attempt to eliminate the free parasites by phagocytosis. For, according to other observers, in cases of malaria in which the large mononuclear and transitional forms constituted about the same percentage of the leucocytes as they did in this case, the polymorphonuclear cells were considerably less numerous.

TABLE II.—*Differential Leucocyte Count.*

Type of leucocyte.	
Polymorphonuclear	58·0 per cent.
Large mononuclear and transitional ...	31·5 ,,
Lymphocyte	10·1 ,,
Eosinophile	0·4 ,,
Total	100·0 ,,

Stephens and Christophers (1908),[5] for example, give the following differential count: small mononuclear, 18·1 per cent.; large mononuclear and transitional, 31·4 per cent.; polynuclear, 50·2 per cent.; and eosinophile, 0·4 per cent. An increase in the polymorphonuclear cells in this instance would, if the percentage of large mononuclear leucocytes were assumed to remain constant, bring the differential count into almost exact correspondence with that found in the case here recorded.

Phagocytosis of the malaria parasites had indeed taken place to a remarkable degree. 200 polymorphonuclear leucocytes and 200 large mononuclear or transitional leucocytes, taken as they came, were counted and examined for pigment and ingested parasites. (See Table III.) Ingested parasites were found to be present in 63·5 per cent. of the polymorphonuclear, and in 33 per cent. of the large mononuclear or transitional cells. In the large mononuclear and transitional leucocytes they were always few in number, generally only one or two; but many of the polymorphonuclear leucocytes were crowded with them. It is noteworthy that in this case pigmented polymorphonuclear leucocytes (26 per cent.) were almost as common as pigmented mononuclear leucocytes (28·5 per cent.), which are generally considered to be pathognomonic of malarial infection; although to say that they are absolutely so is not strictly correct, since pigment may occur in the large mononuclear cells in other conditions, as, for example, in trypanosome infections as the result of auto-erythrophagocytosis.[6]

TABLE III.—*Showing the Percentage of Leucocytes of the Polymorphonuclear and Large Mononuclear Types containing Ingested Parasites and Pigment.*

	Polymorphonuclear leucocytes.		Large mononuclear and transitional leucocytes.	
	Number of leucocytes counted.	Percentage.	Number of leucocytes counted.	Percentage.
Neither ingested parasites nor pigment present	66	33·0	103	51·5
Ingested parasites only	82	41·0	40	20·0
Pigment only...	7	3·5	31	15·5
Both ingested parasites and pigment present	45	22·5	26	13·0
Totals	200	100·0	200	100·0

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the Royal College of Physicians on Dec. 3rd Licences to practise were conferred upon the following three ladies who have previously passed the examinations and have now complied with the by-laws:—Mabel Kate Bishopp, Hilda Grace Johnson, and Mary Woods, Royal Free Hospital.

INSOMNIA AND SUICIDE.

BY C. ERNEST PRONGER, F.R.C.S.ENG.,
CONSULTING OPHTHALMIC SURGEON TO THE HARROGATE INFIRMARY.

FOR a long time past newspaper reports of suicide, associated with insomnia, have attracted my attention. Probably if all the cases in all the papers were collected we should find that annually a very great wastage of human life from this cause alone goes on which might to a great extent be prevented. But we must also bear in mind the thousands of sufferers from insomnia who struggle on, and who do not yield to the temptation to end a miserable existence.

Turning to the report of the meeting of the British Medical Association at Brighton in 1913, I find insomnia the subject of discussion in the Section of Neurology. The opening address, by Sir George Savage, seems to suggest his dissatisfaction with the present knowledge and treatment of insomnia, for he closes his remarks with the words: "Recognising the emptiness of my paper, I leave it for you to fill up." He was followed by Dr. Butter Stoddart, and the discussion was carried on by Dr. Constance Long (London), Dr. Robert Armstrong-Jones (Claybury), Dr. Jamieson (Melbourne), and others. The various kinds of treatment discussed were: sedatives and hypnotic drugs, travel and change scene and surroundings, alcohol in some instances, hydrotherapy, hypnotism and suggestion; and words of warning were also used as to the dangers incident to some of these methods of treatment—for instance, the acquirement of the drug habit and alcoholism. I could find no mention even of error of refraction, and yet, as a result of a long experience, I firmly believe this to be the most constant and most powerful predisposing cause of insomnia, and the careful and skilful correction of it the most reliable weapon we possess in overcoming this malady. No danger attends it, and it does not interfere with any other treatment should such be required.

I fully appreciate the action of exciting causes, such as influenza, shock, worry, prolonged nursing, financial stress, &c., but I feel that these by themselves would not be so harmful were it not that the nervous system had been previously severely taxed by the constant strain induced by slight refractive error. My object is to bring home to those medical men to whom the sufferers from insomnia apply for relief, and especially to those who have not hitherto relied much upon the ophthalmic surgeon for help in these cases, the importance of the correction of refractive errors. To do this I think it will be of more practical utility to relate some of my experiences, egotistical though this may seem, and to illustrate some of the points by cases which have occurred in my own practice, rather than to rake up isolated published cases or to refer to the many papers which have from time to time appeared, and have probably already been read and digested.

For more than 20 years my attention has been especially devoted to the consideration of the influence that slight refractive errors have in causing many of the functional nerve troubles so prevalent in these days. Amongst these insomnia has naturally had a prominent place. In my student days we were taught that slight errors of refraction, anything below one dioptre were of no consequence, and might be ignored. From a purely visual point of view this was true, but as time went on it was observed that these slight errors, although not causing any visual defect, are of great importance in that they give rise to sundry neuroses. For a long time, and even now, the view that the correction of slight refractive errors might be a cure for many functional nerve troubles has been scoffed at and ridiculed, but undoubtedly a change is gradually taking place in this respect. Especially should these slight degrees never be ignored in any case of insomnia, and I think it will be found that some error is nearly always present in those cases not associated with organic disease, such as tumour, kidney troubles, and the like, or with persistent pain from any cause. Insomnia is not usually the only symptom, but is generally associated with attacks of great depression, and often with giddiness or headaches.

It seems unnecessary to quote a number of cases of suicide which I have seen reported in connexion with this subject, for there must be few medical men who have not been more or less brought into contact with such cases, and none who have not frequently read of them. I should like, however, to mention just two cases associated with refractive error which made a great impression on me at the time. The first was that of a gentleman who for some years had suffered from attacks of severe headache and depression, whom I saw on two occasions at an interval of five years. Each time I urged him to wear glasses constantly, but in spite of my appeals to his reason and common-sense he persistently refused to wear them except for reading. Some years later his self-inflicted death was reported, and he had left a letter in which was the passage: "I have fought my nerves for years, but can do so no longer."

Some years ago a pretty little girl, aged 13 years, came to me with her mother, for whom I had prescribed glasses. Very slight drooping of one eyelid, together with a highly strung nervous and shy manner, suggested to me that she had inherited her mother's defect—astigmatism—and on examination I found that this was so, and advised glasses. In this case, too, the mother refused to have "such a child" put into spectacles. I pointed out the possible ill-effects that might arise, but, unfortunately, she decided against my suggestion. When about 19 or 20 years of age the daughter developed symptoms of neurasthenia, and for four years was treated by various methods until finally a "rest cure" was proposed, and she was taken to a nursing home for this purpose. A few days later, in the absence of the nurse, she had destroyed that young life, out of which all brightness and joy had gone.

I will now turn to the brighter side of my paper, and give a few illustrations of what can be done for the relief of insomnia, and also of some of the difficulties that have to be surmounted, particularly the scepticism of the patient as to the possibility of glasses being of use for such a purpose, especially if the sight is good or an oculist has already been seen.

The writer of the following letter was with difficulty persuaded by her doctor to consult me, for she could not believe that her eyes were responsible for the insomnia from which she had been so long a sufferer, as she had seen an oculist, and her glasses were quite satisfactory, so far as she knew, and she could see quite well with them. Fortunately for her, the doctor insisted, and she came. I modified her reading glasses, and ordered some for constant use. Three months later she wrote: "I am sleeping wonderfully better since you saw me in May."

The following was a case of very long standing, but I never despair of relieving any case of insomnia if the patient will carry out my instructions to the letter. He writes:—

> When you stated so confidently that you could cure my insomnia and depression I could not believe it, for I had suffered from these attacks for more than 20 years. They came on at intervals, and lasted for several weeks, and had increased in severity in recent years. While they lasted I felt incapable of transacting any business satisfactorily, *and life did not seem worth living*. Since adopting your remedy I have been perfectly free from any symptoms of this trouble.

A clergyman had suffered for nearly two years from spells of insomnia, accompanied by frequent attacks of palpitation, and a great feeling of "nervousness." The doctor who sent him to me diagnosed these conditions as due to eyestrain, which proved to be the case, although he would have passed the visual test as "practically normal." He reported subsequently:—"The effect of the glasses has been decidedly good. 1. The palpitation has passed away. 2. The nerves are quieter, and normal sleep has returned. You have a most grateful patient, I assure you."

What a number of our own professional brethren have perished as the result of insomnia and nervous breakdown, and the verdict has been suicide, or, more mercifully, "misadventure." I have seen many who have been very near such an end, and patients have often told me afterwards how greatly they had been tempted. I remember very vividly the case of a comparatively young doctor, about 38 years of age; and his professional brother, who was attending him, came to talk over the details before sending him to me, and expressed his anxiety as to suicide or insanity. He had been taking drugs for his insomnia for some time, and his depression was extreme. It can well be imagined with what pleasure I read the letter which came from him about six months later. I may say that he had had glasses previously to my seeing him, but had not experienced much need of them, and had used them very little. He writes:—

> I am at present doing double duty, as my colleague is away through illness, so you may guess I am feeling very fit to be able to cope with this difficulty. I am glad to tell you that the giddiness, insomnia, and other nervous symptoms have all disappeared, and I am now feeling bright and energetic—in fact, as well as I have ever felt in my life. Of course, I wear religiously the glasses you ordered for me. Do you remember how I complained of most acute nausea and heart distress when travelling by rail? Well, that has also completely gone. I shall always feel grateful to you for what your skilled advice and sympathetic treatment have done for me, and I can conscientiously say that I can attribute my improvement to nothing else.

By treating what I look upon as the initial cause of insomnia or nervous breakdown, we are able to anticipate more permanent results than are usually obtained from the use of drugs and other forms of treatment, which are in many cases only palliative and temporary in their effects. This point is well illustrated in a case reported in a former paper of mine published in THE LANCET[1] nine years ago on Slight Errors of Refraction and their Influence on the Nervous System, and I will briefly refer to it again. The patient, a minister, had suffered for two years from severe headaches, insomnia, and giddiness, resulting finally in a complete nervous breakdown. He had given up all hope of ever being any better, and he told me later that he dared not sleep in an upstairs room, and had given up shaving as he was afraid he might yield to the temptation to commit suicide. The doctor had the usual difficulty in getting him to come to me, as he had seen an oculist in London, and was using glasses with which he could see quite well. I changed his glasses for reading, and gave him glasses for constant use, and he wrote me six months later: "After ten weeks of hard and anxious work I am still holding my own. Refreshing sleep has become habitual, after a long period of insomnia, during which I was quite a wreck, as you know, and with sleep strength began to return, and life, which had been a burden, is now a delight." This patient has been to see me recently and tells me he has been actively engaged in his work since his visits to me in 1903.

---

[1] THE LANCET, June 10th, 1905, p. 1573.

Another very interesting case occurred in my practice a few years ago, but in this instance giddiness was a more pronounced symptom than insomnia. A lady had suffered from severe attacks of giddiness for several years, becoming so giddy that she was afraid to go out of doors unattended, frequently had to leave the breakfast table, and if she went to church invariably had to come out. She had sought advice from many physicians in Belfast, Dublin, and London, but without relief, and ultimately came to Harrogate. She was somewhat taken aback when the doctor whom she consulted here after a careful examination and a patient hearing of her history advised her to consult me. She at once said she had already seen the first oculists of the day, and quoted the names of six whom she had consulted. Probably most doctors would have accepted that statement as final, and given up all idea of further treatment in that direction. Fortunately for the patient that did not happen, and I saw her. I gave her glasses, both for distance and reading, and she soon began to improve, and wrote me 12 months later:—

> You will be pleased to hear that I have had practically no vertigo, have had no prolonged attacks since with you last July, and even the swift little turns have not troubled me now for some months. I never have to leave the table, and, indeed, may say that I am practically free, as I go on the roads freely and never feel distressed, so if that only continues I shall be the happy woman I am at present.

Does this case not show that it is absolutely necessary, firstly, that the physician should be aware of slight refractory error as an initial cause of insomnia, and, secondly, that the ophthalmic surgeon to whom he may send the patient should also be aware of it, and should possess the combination of care, perseverance, and skill necessary for the detection of very slight errors, accuracy in estimating the amount of such error, and tact and judgment in getting his treatment effectually carried out? Failure resulted in this case up to a certain point from a lack of this combination, but in the end complete success was achieved by the confident persistence of her Harrogate doctor, together with the pair of spectacles she obtained in consequence of it.

The writing of my paper was at this point interrupted, and in the short interval of 24 hours before resuming it rather striking coincidences have taken place. In the first place, in my daily paper another of those painful suicides is related; the rector of a parish having written the following letter, was found dead in a pool with a bullet wound in the head: "Another sleepless night; no real sleep for weeks. Oh, my poor brain, I cannot bear the lengthy, dark hours of the night; dazed, confused, I know not what I am doing. God have mercy on me, and raise up friends to my poor wife." Do not these cases cry out to us for more strenuous efforts?

As illustrating the prevalence of it, three patients have in that short time sought my advice for insomnia, one from Ipswich, one from Dublin, and one from my own town, Harrogate. The last, after trying various methods of treatment for nearly two years, tells me that it has at last been suggested by a specialist in London that his eyes might be the cause of his trouble; and that undoubtedly is the case.

Thus far I have given a few illustrations of cases of long standing and of severe type, and if it is possible to give complete relief in such, may we not entertain great hopes for the future? Is it not also an inducement to those who have hitherto been sceptical to test the matter thoroughly for themselves, and gradually to acquire that experience which is so necessary for the surmounting of those many difficulties one meets with in obtaining satisfactory results? The natural inference, too, is that if cases of this kind were seen in the early stage there would be a ready response to treatment; and, if so, what a contrast financially alone to those of limited means—a pair of spectacles *versus* a sea voyage, three or four months in Switzerland or elsewhere, six or seven weeks in a home for so-called "rest cure," and so forth.

A few letters will suffice to demonstrate this ready response to treatment. A doctor who was perilously near a nervous breakdown was enabled to continue his work and wrote:—

> I have persevered continuously with the glasses you prescribed for me in May last with the greatest satisfaction. There is distinct improvement in the tone of my general health, and the depression, irritability, and insomnia are relegated to the memories of the past. I could not have anticipated such good results, and tender my sincerest thanks.

The following case of nervous breakdown from insomnia and dyspepsia occurred in India. The patient was sent home to consult a certain physician in London, and ultimately came for a course of treatment to Harrogate. After being here six weeks he was in despair as he had derived no benefit. A friend of his then suggested that he should see me. He was much surprised, as he had particularly good vision, but came nevertheless, and the constant use of glasses soon helped him. He wrote from India:—

> It is now nearly six months since I was fortunate enough to come under your care, and I am writing to let you know how I have fared. From the time I started to wear my glasses I began to feel an improvement in my general health, so much so that before I left home in December last I was feeling much better in every respect, and since my arrival in India I have continued to mend until now I feel more or less like my former normal self—in fact, an altogether different man, both eating and sleeping well, whilst my indigestion is almost a thing of the past.

A similar case, a doctor of music, writes: "I am glad to tell you I am in really good health again. I sleep well and my nervous system is stronger than it has been for a long time. All my work, both public and private, has been quite satisfactory and I can now enjoy life."

Before closing this paper may I venture on just one suggestion as to the great prevalence of functional nerve troubles and the cause thereof? I have often heard two special causes mentioned, "the strenuous life of the present day" and "the influence of heredity." With both of these I cordially agree, if I may supplement them thus: "The influence of the strenuous life upon those whose nervous systems have been already considerably taxed by the presence of refractive error." Do we not see many men leading the most strenuous lives possible, and yet whose nervous systems never falter, and, on the other hand, those whose nerves are shattered, but whose lives have been anything but strenuous? As to heredity, its influence is shown in that the *initial cause* of the neuroses—*refractive error*—in one generation is so frequently *transmitted*, and gives rise to similar neuroses in the next. Do we not have instances of two brothers, or two sisters—the one with a normal, evenly balanced nervous system and normal refraction, the other with *inherited refractive error*, and the highly strung *neurotic* temperament?

It is my firm conviction that it is from the more general recognition, both by physicians and ophthalmic surgeons, of what I have indicated as the initial or predisposing cause, and the earlier and more effectual treatment of it, that we must hope for a diminution of this appalling number of suicides, and that relief and happiness may be brought to that vast number, who, victims of insomnia and neurasthenia, or "nervous breakdown," are dragging along a miserable existence.

Harrogate.

EXPERIMENTS ON THE GERMICIDAL ACTION OF COLLOIDAL SILVER.

BY W. J. SIMPSON, C.M.G., M.D. ABERD., F.R.C.P. LOND.,
PROFESSOR OF HYGIENE, KING'S COLLEGE, LONDON;
AND
R. TANNER HEWLETT, M.D. LOND., F.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON.

SOME years ago Mr. Henry Crookes[1] observed a peculiar action of some metals in inhibiting the growth of bacteria in their neighbourhood. This was afterwards recognised as being due to a germicidal action brought about by the metals being in a colloidal state. We have recently carried out some experiments on the germicidal properties of colloidal silver in the form of a liquid, collosol, prepared by Mr. Crookes. The experiments were all carried out on the typhoid bacillus by the following methods:—

1. *By the Rideal-Walker or drop method.*—In this the disinfecting power of collosol on the typhoid bacillus in water was compared with that of phenol under identical conditions, the maximum period of exposure to the disinfectant being 15 minutes. We have found that within this period even a 1 : 2000 solution of collosol does not kill the typhoid bacillus (i.e., within 15 minutes), this being only just accomplished by a 1 : 500 solution. This result indicates that collosol would be somewhat slow in acting if used as an ordinary disinfectant. The preparation is, however, too expensive to be employed and is not suggested for this purpose.

2. We next tested collosol by the method suggested by Mr. Crookes—viz., the collosol solution was mixed with nutrient broth so as to give a 500 per 1,000,000 strength. Other dilutions of this were prepared—viz., 100, 50, 25, 10, and 5 per 1,000,000 with nutrient broth, and six tubes, each containing 10 c.c. of these various dilutions, were prepared and inoculated with one drop of a 24-hour broth culture of the typhoid bacillus. The inoculated tubes were incubated at 37° C. and subcultures were made after 24 hours. It was found that no growth occurred in the inoculated tubes except in the weakest dilution (5 per 1,000,000). Subcultures made with three loopfuls from these tubes similarly showed no growth with the exception of the subculture made from the 5 per 1,000,000 dilution.

As the determinations made by the Rideal-Walker method indicated that a greater strength than this—viz., 1 : 500—would be required to be efficient for short exposures, experiments were made as above by the method suggested by Mr. Crookes, but subcultures were made from the inoculated tubes at 15 minutes, 30 minutes, one hour, and two hours after inoculation, in addition to 24 hours. The result was that growth occurred from most of the dilutions after 15 and 30 minutes' exposure, as shown by the following table:—

—	Subcultures made after					Original tubes after three days.
	15 min.	30 min.	One hour.	Two hours.	24 hours.	
500 per million	+	0	0	0	0	0
100 ,, ,, ...	0	0	0	0	0	0
50 ,, ,, ...	+	+	0	0	0	0
25 ,, ,, ...	+	+	0	0	0	0
10 ,, ,, ...	+	+	+	0	0	0
5 ,, ,, ...	+	+	+	0	+	+

+ = growth; 0 = no growth in the subcultures.

This again shows that collosol is somewhat slow in acting, the best results being obtained only after more than one hour's exposure. It was thought that it might be interesting to test mercuric chloride in the same manner for the sake of comparison. A fresh 1 : 500 aqueous solution of mercuric chloride was made and diluted with broth in precisely the same manner as the 1 : 500 collosol, and tested as in the last-named experiment. The results were as shown in the subjoined table.

—	Subcultures made after					Original tubes after three days.
	15 min.	30 min.	One hour.	Two hours.	24 hours.	
500 per million	+	0	0	0	0	0
100 ,, ,, ...	+	0	0	0	0	0
50 ,, ,, ...	+	+	0	0	0	0
25 ,, ,, ...	+	+	0	0	0	0
10 ,, ,, ...	+	+	+	+	+	0
5 ,, ,, ...	+	+	+	+	0	0

Ammonium sulphide was added to neutralise any mercuric chloride carried over. The results obtained with mercuric chloride are therefore very similar to those obtained with collosol, but if anything the mercuric chloride proved more inhibitory than collosol in the original tubes. It is to be noted that in the presence of the peptone, &c., of the broth the mercury is largely transformed into a colloidal state and evinces its great activity.

There can be no doubt from the foregoing experiments that colloidal silver in the form of collosol is an active germicide. We understand that the collosols are non-poisonous and have been administered internally.

---

ROYAL INSTITUTION.—The managers have elected Professor C. S. Sherrington, M.D., F.R.S., to be Fullerian professor of physiology for a term of three years dating from Jan. 13th next. Among the lectures arranged to be given at the Royal Institution before Easter are three by Dr. Henry G. Plimmer on Modern Theories and Methods in Medicine: (1) Medicine and Science; (2) Immunity; and (3) Methods and Results. Dr. Chalmers Mitchell will give three lectures on Zoological Studies: War and Evolution. Sir Rickman Godlee is announced to give one of the Friday evening discourses, which will begin again on Jan. 22nd.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases.—Necessity for an Exact Definition of Blindness.

A MEETING of this section was held on Dec. 2nd, Mr. PRIESTLEY SMITH, the President, being in the chair.

The PRESIDENT made sympathetic reference to the death on the battlefield of Mr. Angus MacNab, an active member of the section, and proposed a resolution of sympathy with his family, which was passed.

Dr. ROSA FORD showed a case in which an Eyelash Pierced the Lid Border backwards.

Sir ANDERSON CRITCHETT showed a patient with Small Optical Iridectomies in a case of lamellar cataract. He described the operation, which was initiated by his father 50 years ago, and narrated cases so treated in which the result was very permanent.—Mr. W. H. H. JESSOP spoke favourably of the procedure, which he had himself carried out with great success in adults as well as in children. In one case operated upon 22 years ago the result was as good to-day as at the time.—Dr. ANGUS MACGILLIVRAY said he had done the operation described several times. The results by removal of the lens were not as satisfactory in lamellar as in other forms of cataract.

Mr. LESLIE PATON showed a case which he regarded as Mikulicz's disease, and gave his reasons for the view.—Colonel R. H. ELLIOT referred to a case of the disease which he published in the *Ophthalmoscope*—that of a Hindu woman, aged 49, in whom the lacrymal glands on both sides bulged like short horns, and the accessory portions of these glands projected into the conjunctival sac. The parotid, sublingual, and submaxillary glands showed fulness. Removal of the lacrymal not only improved the appearance, but was followed by subsidence of the other glands. The tissues removed presented a close resemblance to the appearance of round-celled sarcomata.

Mr. H. ROBINSON exhibited a case of Irido-cyclitis, and Mr. H. L. EASON one of Bilateral Temporal Hemianopia, to illustrate the importance of taking the fields of vision in every case of optic atrophy. The patient, though he had seen many ophthalmic surgeons, became so blind that he had to be led about. His fields had not then been tested. He could make out moving objects and lights on the nasal side only. The onset of blindness within six months was unlike the history of the optic atrophy of tabes, and Mr. Eason thought he might have pituitary tumour. Within a month of taking thyroid he got remarkable improvement of vision. He still took the extract, for if he went long without it he noticed a relapse. The sella turcica was somewhat enlarged.

Mr. W. T. HOLMES SPICER showed a case with Angeioid Streaks.

Mr. HAROLD B. GRIMSDALE, in opening a debate on the Necessity for an Exact Definition of Blindness, stated that the importance of defining, if possible, the condition of blindness had long exercised the minds of those concerned in the teaching and maintenance of the blind, and the recent awakening of public interest in the question made it all the more urgent to clear away doubt. On the recently appointed committee on the subject he was the sole representative of ophthalmic surgery; he had therefore invited this section of the Royal Society of Medicine to try to arrive at something like unanimity on the question. Many members of the profession whom he had asked found it impossible to define the status of a blind child otherwise than was done in the Act of 1893—namely, that for educational purposes a child shall be considered blind who is too blind to read the ordinary school books. Yet all children who did not come into this definition were not fit for the ordinary school—for instance, subjects of high myopia. It was desirable to have some rule for evaluation as a guide in each case. Many factors must be taken into account, and these concerned both the state of the patient and his employment. Both central acuity and the state of the peripheral vision must be considered, as well as the relative value of the two eyes, and the presence or absence of binocular vision. For certain employments a greater acuity was needed than for others. Those having no perception of light were but a small proportion of those ranked among the blind, while among children the proportion was still smaller. Among adults the blindness from optic nerve atrophy and glaucoma led to a preponderance over children. In a blind school of 68 children 8 had no perception of light. In Boston, Mass., of 2021 eye patients 0·6 per cent. were totally blind, 7·7 per cent. "practically blind," with a vision less than 6/60 of normal. These figures were not a guide, because totally blind persons would not seek relief. The blind persons in the United Kingdom number about 27,000, according to the Census, but this could not be accurate. The ratio of the totally blind to the economically blind was about 1 to 9. The causes of economic blindness in children differed considerably from those in the adult. In the former, the chief trouble was loss of central acuity from corneal conditions, while in adults disease of the optic nerve with contraction of the visual field operated chiefly. There was evident a tendency to make the standard of vision too high, and thus throw a large number of children into the "blind" class. One reason was that a child with bad sight demanded more individual attention from his teachers than the others, and so constituted a drag on the class as a whole. This was a stimulus to put such child into a special school. This might ensure his education being better looked after for the time, but once labelled "blind" he was liable to be drafted into a blind workshop. The co-education of the blind and the seeing was one of the most interesting experiments which had been conducted; the blind child was first started in a special school until he had mastered the elements of Braille writing and reading; then he took his place among sighted children in the universal school, and often competed successfully with normal children. The capacity to read separate letters was a very different matter from being able to read words; from experiments he found that the "near" acuity as measured by reading words was often more than twice the distant acuity measured on single letters. Often so-called blind children tried to read Braille by sight in preference to by touch. He contended that between the "blind" school and the normal school there should be a third school for children who had such visual defect that they could not be taught by the aid of the blackboard. His suggestion was that a distant acuity of 6/60 should be taken as the highest limit of vision for a blind school child. Those whose vision was better than 6/24, unless otherwise recommended by a medical man, he would send to an ordinary school. All special schools should be inspected at least once a year, and the vision of each child tested and recorded. Among the blind there would always be two classes: those who could not see at all or scarcely so, and those who could distinguish large objects, and so could guide themselves by their eyes in unfamiliar surroundings. Given a good field an acuity of well below 3/60 enabled a man to move freely in the outside world; hence he regarded 6/60 as too high a standard below which a man should be regarded as practically blind. Mr. Grimsdale then dealt with the question in relation to various trades, and in conclusion suggested the appointment of a subcommittee to deal with the question in all its bearings. It was undesirable that a Bill on the subject should pass through Parliament without any reference to the opinion of that section of the Royal Society of Medicine, for in that case most difficult questions would be left to the decision of absolutely unqualified amateurs.—Mr. W. M ROCKCLIFFE said that for many years he had advocated some definition of blindness. The Local Government Board defined blindness as "Too blind, in the opinion of the Local Government Board, to perform work for which eyesight is ordinarily required." Others expressed it as "Blind for the practical purposes of life." During 30 years he had examined and admitted into a blind school large numbers, and his decisions had not been questioned. He divided cases into (*a*) blind and (*b*) partially blind. The latter were those who were able to differentiate fingers at a greater distance than three feet. There should be a clear distinction drawn between capacity for ordinary school education and for technical education. A good broad distinction was those who could count fingers at three feet and those who could not. There should be a clear decision as to who should be participants in pensions for the blind. —Dr. MACGILLIVRAY said that for industrial purposes so-called blind people could be divided into three classes: (1) totally blind, those who had no perception of light; (2) practically blind, those possessing perception of light but were unable to take part in industrial occupations owing to marked impairment of vision; and (3) the partially blind, whose defect prevented them obtaining employment in ordinary sighted workshops, their vision yet being such as to disqualify them from entrance to a blind institution. 30 per cent. of the inmates of blind institutions belonged to the category partially blind. He discussed the case of children and the general question in relation to occupations. —Mr. N. BISHOP HARMAN contended that there was only one exact definition of blindness—the dictionary one—"want of sight." But the term was used to include many varieties of partial blindness, and for those that definition was sought. Vision was a complex act: acuity, field, mobility, mentality, and effects of difference of lighting, habit and custom, all took a share in the sensation. It was not possible by any sufficiently simple definition to gather up possible varieties, any one of which might constitute partial blindness of serious order. Any definition must be related to the facts of life, must have reference to the person's capacity for work. If it could be certified that he was incapacitated from engaging in profitable labour by reason of his defect, his was a state of blindness. Any attempt to pass a definition of blindness drawn in professional terms, to operate through the Legislature, was, he contended, doomed to failure, and was liable to be altered out of recognition. The definition in the Elementary Education Act, "inability to read the ordinary school books used by children," was worthy the judgment of Solomon, for it defined blindness in terms of life. He pointed out the parallelism of the case of mental defectives, in which also reference was to life. He advocated a certification of blindness by two independent and duly approved medical men, who should be required to state their opinion, and the facts upon which that opinion was based; such opinion being subject to the scrutiny of the medical officer of the proper authority.—Mr. F. RICHARDSON CROSS thought the Legislature was rightly attacking this question. If a child's sight was such that it could not attend the ordinary school, some other arrangement for its education must be made. There were blind schools for those nearly blind, and intermediary schools for myopes. Anything brought forward to deal with the infirmity in adults would not influence the good work being done for the children. Ophthalmic surgeons should agree among themselves as to a proper definition of a blind person. He thought it would be unsound to take the view that the layman was unable to judge on this matter. He thought the Registrar would accept two classes. One would embrace those who had no more than perception of light; the other either Snellen's types or finger-counting, the latter for preference. Anyone who could not count fingers at a greater distance than a yard should be regarded as practically blind. In order to be practical he thought that at first there should be some sacrifice of scientific precision; this could perhaps be arrived at later.—Mr. HOLMES SPICER contended that the persons to decide this question should be expert ophthalmologists, not lay members of a county council. Any rules arrived at should be for the guidance of expert examiners.—The PRESIDENT pointed out how well qualified this section was for giving expert advice on such a matter, which was of the first importance.

MEDICAL SOCIETY OF LONDON.

Discussion on Tetanus.

A MEETING of this society was held on Dec. 7th, Sir JOHN BLAND-SUTTON, the President, being in the chair.

Captain D. EMBLETON, R.A.M.C.(T.), opened a discussion on Tetanus, with special reference to: (*a*) prophylaxis; and (*b*) the serum treatment of established tetanus, dosage, and method of administration. He said he had had the opportunity of observing, both at the 3rd London General Hospital and recently at Netley, a series of cases showing a very varied picture of the disease. The discussion, he understood, was to be limited to the prophylaxis and the serum treatment of established tetanus. Before considering either of these points two features of the B. tetani must be clearly remembered: (1) the spore; and (2) the fact that the B. tetani was a strict anaerobe. With regard to the spore, it must be remembered that it was exceedingly difficult to kill. It would almost withstand dull red heat and a 1 in 20 solution of carbolic acid took 15 hours to kill it. The disease was produced by the inoculation of the spore, which subsequently developed into the bacillus under suitable circumstances. The inoculation of a *clean* spore—that was to say, a spore which had been washed free from its toxin—would not produce the disease, for it was rapidly dealt with by phagocytosis, &c. In order to produce the disease with a clean spore it was necessary to inoculate at the same time some lactic acid, or some other organisms, or to produce considerable trauma, all of which processes lowered the vitality of, or killed, the tissue locally. With regard to the anaerobicity of the B. tetani in artificial culture the organism would only develop when oxygen was excluded. This had led to the idea that the B. tetani would only develop in the body under similar anaerobic conditions. It was questionable, however, if this careful exclusion of oxygen was necessary in the body for the development of the B. tetani and other anaerobes. For example, there were two organisms which produced septicæmia and multiplied in the blood stream—the B. influenzæ and the B. Welchii. The B. influenzæ would develop artificially only in the presence of oxygen, the B. Welchii only in its absence. This suggested that the presence or absence of oxygen, though important in artificial media, played no essential part in the development of an organism in the body. It had also been shown that the B. tetani would grow artificially without any anaerobic precautions in the presence of other bacteria such as the staphylococcus aureus. Again, Tarozzi's method of cultivating an anaerobic organism was important. Tarozzi showed that if a piece of sterile tissue, such as a piece of guinea-pig's kidney, was placed in an ordinary broth culture the B. tetani would develop even if no further precautions were taken for the exclusion of oxygen. On considering this point it became evident that the piece of organ in the broth must undergo autolysis or self-digestion, and this suggested that tissue undergoing autolysis was important for the development of the B. tetani. A clean tetanus spore would only give rise to tetanus when the tissues were damaged, and damaged tissues underwent autolysis. Thus it would seem that the dead autolysing tissue rather than the exclusion of oxygen was important for the development of the disease. He then considered the nidus and migration of the organism. The B. tetani was said to occur in the disease at the site of inoculation and in the nearest lymph glands only. If this were true it was different to all other bacteria, which seemed improbable. Similar statements had been made concerning various diseases, such as diphtheria and cholera; of both these diseases the organisms had until recently been said to occur only locally, but careful investigation had shown that they could be demonstrated in the marrow and spleen. It was practically certain that the tetanus bacilli migrated rapidly by way of the lymphatics to the thoracic duct, and thus entered the blood stream and became disseminated throughout the body. The majority of organisms were then undoubtedly destroyed, though it should be possible to demonstrate them in the bone marrow, spleen, and urine. The fact that the organisms had not yet been demonstrated was probably due to the rarity of the disease and the difficulty of cultivation. (He, unfortunately, had not yet had an opportunity of searching for them in the human.) It was thus possible that the so-called tetanus toxin might be liberated from many points in the body as well as from the original focus, and this might account for the first spasms starting, as they frequently did, at a distance from the original lesion. It had been recently stated before the society[1] that if a wound was swabbed out with pure carbolic acid tetanus and sepsis would be practically abolished and wounds would heal by first intention. Against this assertion might be raised the following points. 1. 1 in 20 carbolic acid was the most efficient germicidal dilution of phenol. Pure carbolic acid was no more potent than a solution of 1 in 20. 2. 1 in 20 carbolic acid took 15 hours to kill tetanus spores. The disease was caused by spores. 3. It damaged the tissues, and these damaged tissues would subsequently undergo autolysis. 4. Kanthack used broth having a strength of 1 in 20 carbolic acid to isolate and cultivate the tetanus bacillus. 5. Dr. F. H. Thiele and he (Captain Embleton) had also shown that carbolic acid (1 in 20 or pure) swabbed on to a wound artificially produced in a guinea-pig and infected with spore-bearing organisms would not protect the animal, even when applied two minutes after the infection had been produced, the bacteria even in this short time having migrated beyond the range of the antiseptic. To sum up, pure carbolic acid appeared to be of little value in the prevention of tetanus and in the treatment of septic wounds, and, in fact, by damaging the tissues, seemed dangerous. The same argument also applied to the use of other strong antiseptics. The fact that the tetanus bacilli had only been demonstrated in the wound and the nearest lymph glands showed that the blood could deal with the organisms as long as it could gain free access to them. This suggested that in cleaning the wound no substance likely to damage the tissues should be used and that free access of blood to the part should be ensured either by hot baths, fomentations, or Bier's method. He then dwelt on the prophylaxis. The value of antitetanic serum for prophylactic purposes he held had been definitely established, both experimentally on animals and also from statistics in the case of man. It was probable that nearly every wound received by our troops operating in the highly manured districts of France and Belgium was infected with tetanus spores, but only a relatively small number of cases of tetanus occurred. Theoretically every wound should thus be treated with serum. This, of course, would be practically impossible. It had been suggested that since all wounds could not be treated prophylactically only shell and shrapnel wounds should be so treated; this would include the majority of cases, but he had seen a case of tetanus in a man wounded with a rifle bullet. The probability of tetanus arising appeared to depend upon the extent of laceration and consequent liability to infection and not on the nature of the projectile. With regard to the prophylactic dose of antitetanic serum much work had been done and the results were well known. It was manifestly impossible to lay down hard-and-fast rules as to what was and what was not a prophylactic dose. One frequently had to decide what dose was to be given and when, to a man who was to be operated upon and who had been exposed to tetanic infection several days previously. It must be borne in mind that the patient might be in the incubation period of tetanus, and might have a large nidus which would be stirred up during the operation. Ideally, at the time of operation a sufficient dose of antitetanic serum should be circulating in the patient's system. It seemed probable that 6000 units some three hours before the operation should suffice. He then considered the treatment of established tetanus. He said that with regard to the use of hypnotics it should be remembered that these were given not to cure the disease but to relieve symptoms which were otherwise inimical to life, such as fixation of the chest and suffocation, or continuous spasms, producing marked mental distress and exhaustion. On the other hand, the central nervous system was being severely poisoned by the tetanus toxin, and unless there was urgent need for the use of hypnotics it would seem safer to withhold them. The hypnotics which seemed to have given the best results were chloral and bromide or chloretone, and for rapid action paraldehyde and ether suspended in saline and administered intravenously. It had been proved experimentally on animals that the administration of antitetanic serum in established tetanus was of value. To be of use, however, the serum must be given very soon after the first appearance of the symptoms. In man the value of serum treatment was still doubted by many. It had been shown, however, that if the dose given was very large the beneficial results following the use of serum became manifest. It had been stated that if the cranial nerve nuclei other than the fifth were involved the patient would die whether serum was given or not. If the cranial nerves were not involved it was probable that the case would recover without any treatment. This he was not inclined to agree with without further proof. It had been shown that the so-called tetanus toxin gained access to the central nervous system along the axis cylinders of the nerves, and had been suggested that the antitoxin should be injected into the nerve trunks running to the lesion, under the impression that the serum would neutralise the toxin and prevent its passing to the central nervous system. Non-diffusible substances such as serum would not pass up the axis cylinders, but would run up the perineural lymphatics to the intervertebral foramina where these lymphatics left the nerves. The routes of the toxin and antitoxin were thus different. *Intrathecal inoculation* of antitetanic serum had been much advocated in the treatment of established tetanus on the assumption that the antitoxin could by this means get into rapid and intimate contact with the toxin in the affected nerve cells. This was based upon an erroneous conception. There was no evidence that non-diffusible substances such as serum could penetrate to any depth into the nerve tissue when injected either into the subarachnoid space or into the lateral ventricle. On the other hand, there was experimental evidence that it could not do so. Substances inoculated in this way rapidly passed into the big venous sinuses and lymphatic channels. Thus, this method was merely another way of giving an intravenous inoculation. Roux had published a series of experiments in which he got very satisfactory results by injecting antitoxin into the frontal lobes, but non-diffusible substances such as serum when injected into the brain either leaked back along the track of the needle and so reached the cerebro-spinal fluid or remained localised at the point of inoculation. Flexner's experiments with poliomyelitis virus showed that in the case of an infection the infection could in time spread from an inoculation in the cerebral lobes to the cord. Thus it was possible that a small amount of tetanus antitoxin might be directly absorbed and pass along to the affected areas. Roux's experiments were, however, definite, and it was necessary to re-examine them from other points of view. In tetanus the tension in the cerebro-spinal fluid had been found to be very much increased. It was possible that the relief of tension followed by a pouring out of fresh fluid might have produced the same beneficial results in tetanus as it did in meningitis. The amount of serum that could be inoculated by this route without severely lacerating the cerebrum or ploughing a way into the ventricles or subarachnoid space was exceedingly small. The *intravenous route* for the injection of serum would probably be the easiest and best, but it had this danger, that it might produce acute anaphylactic symptoms or death in a person primarily hypersensitive to horse serum or in a person who had previously been inoculated with an antiserum of any sort prepared from the horse. The *subcutaneous route* was undoubtedly the safest, since the absorption was slower and violent anaphylactic symptoms were less likely to occur. The absorption, however, was sufficiently rapid for the purposes of treatment, and very large quantities could be given. It would take too long to discuss the nature of the toxin and the mode of interaction of the toxin and antitoxin, but he believed that the toxin was produced by the digestive action of the serum or tissues of the infected animal on primarily non-toxic tetanus protein; and that the action of the antitetanic serum was to hasten this process of digestion, so that there was no accumulation of such toxic substances. The object of administering antitetanic serum was to (1) destroy the circulating toxin; (2) promote phagocytosis of the tetanus bacilli; and (3) destroy the toxin already causing symptoms to the central nervous system. Immediately after the first symptoms of tetanus appeared, 10,000 units should be inoculated, and subsequently 3000 units every two hours until the symptoms abated. The inoculation of serum should not, however, be continued beyond the third day, for by this time the tissues would have become sensitive to horse serum, and would produce from the horse serum toxic anaphylactic substances, and at the same time would destroy the antitoxin of the serum, so that it would be of little value. Hypnotics should be withheld until the severity of the spasms or the exhausted condition of the patient demanded relief. When given they should be exhibited in sufficient quantities to produce a marked effect.

---

[1] THE LANCET, Nov 21st, 1914, p. 1200.

Professor F. W. **ANDREWES** urged that the tetanus bacillus was not an inhabitant of soil, as such, but of the animal dung with which cultivated soil is mixed. The risk of tetanus was that of deep implantation in wounds of cultivated soil or other matter polluted with the dung of horses or cattle. In any given wound this risk might be roughly estimated by the evidence of such contamination either on clinical or bacteriological grounds. The bacteriological test on which he was disposed to place chief reliance was the presence of anaerobic bacilli in the wound discharges. A smear of the pus stained by the Gram-fuchsin method was commonly a sufficient clue to their presence. Unless an unlimited supply of antitoxin was at hand it was necessary to exercise some selection of cases in the administration of tetanus antitoxin as a prophylactic. He considered the presence of large Gram-positive bacilli, resembling B. aerogenes capsulatus, a good indication for a prophylactic dose of serum. The evidence went to show that 500 U.S.A. units was an adequate prophylactic dose in ordinary cases, since it is known to be enough to protect a horse. 1000 units might be safer in a severe and very foul wound, or one in which a considerable time had elapsed since its infliction. He considered it right to give serum in a suspicious wound, even though two or three weeks had passed since the infliction of the injury. As regards the treatment of the declared disease Professor Andrewes expressed himself in favour, on theoretical grounds, of amputation or free excision of the wound, where this was possible. The route of administration of antitoxin which he advocated was the intrathecal one, as being better than the subcutaneous or intravenous routes and safer than the intracerebral one. Statistics showed clearly that, when employed, antitoxin should be given in large doses—15,000 or 20,000 U.S.A. units repeated as necessary. As an adjuvant to keeping up a high concentration of antitoxin in the central nervous system, large doses should also be given subcutaneously. More, however, could not be expected from antitoxin than that it should turn the scale in doubtful cases. In the use of sedatives for the palliation of pain and other symptoms it must be remembered that death was often due to respiratory complications, and that such drugs as morphia might in some circumstances be dangerous.

Dr. **JOHN EYRE** said that he was quite in accord with what Professor Andrewes had said with regard to the value of finding Gram-positive organisms resembling B. aerogenes capsulatus in the discharge from an infected wound, but he had met with several cases of tetanus in which they were not found. Inoculation of a mouse caused tetanus after two or three days. It was clear, therefore, that a decision as to treatment must depend mainly upon the surgical aspect of the case. Badly lacerated, contused, or deeply incised wounds were those which should be chosen for prophylactic treatment against tetanus. Referring to treatment with carbolic acid, he pointed out that the spore was not the entity which gave rise to the toxin, but the bacillus, which was very susceptible to the influence of carbolic acid. The site of production of the toxin should, in his opinion, be dealt with as soon as possible. With regard to the prophylactic dose, 500 units probably afforded good protection if they could be used immediately. The amount required, however, increased rapidly with delay, and at the end of 24 hours from infection 20 or 30 times as much was needed. The serum conferred immunity for about a week, and at the end of that time a second dose was necessary. When tetanus had become established, though on theoretical grounds, it was well to get rid of the site of manufacture of the toxin, in experimental work infection did not remain localised to the focus of inoculation. He thought that intracerebral injections, in view of the grave lesions produced, should only be used as a last resort, though they sometimes seemed to turn the scale. The intrathecal route was the most important and efficient. In his own experience cases treated thus had usually recovered, whilst those only receiving subcutaneous injections had usually died. The cerebro-spinal fluid was often under considerable pressure and ran freely away, so that a considerable dose of serum could be given. Intravenous inoculation acted quickly and subcutaneous slowly, but the latter kept up a persistent dosage. He advised that all three methods should be employed simultaneously.

Lieutenant **R. B. BLAIR**, R.A.M.C., said that he had treated 17 cases of tetanus at the Herbert Hospital, Woolwich; 6 had died, 9 recovered, and 2 were still under treatment. Ten cases were very acute. The wounds were mostly severe and all very dirty. They were generally gunshot wounds, not shrapnel. In 4, prophylactic doses of serum had been given before they entered the hospital; 3 of these had died, and it would seem that the doses they had had were small and not given early enough. He thought that unless the patients were seen within two days 4000 units should be given intraspinously. The treatment which he had employed at the hospital for the cases of established tetanus was intrathecal injection of 4000 units daily. No difficulty had been experienced using a light anæsthesia. The cerebro-spinal fluid was under very great pressure; it was allowed to run until it began to drop slowly and then the serum was injected, the volume introduced being less than that which ran away. The hypnotics used were morphia, chloral and bromide (60 grains of each 2 or 3 times in the 24 hours), and chloretone (40 grains in 2 ounces of olive oil, 2 or 3 times daily, per rectum). When the chloretone was retained it relieved the spasms for several hours, but it was often rejected. Stimulants might be necessary if exhaustion appeared. It was seldom necessary to amputate the limb during the attack of tetanus; in the few cases in which this had been done all but one succumbed. The total quantity of serum given varied greatly, 62,000 units being the maximum amount which had been employed.

Dr. **CARL H. BROWNING** said that one point was clear, that the amount of serum required grew enormously with the lapse of time from infection. Consequently, the earliest symptoms of tetanus must be carefully watched for. The danger of anaphylaxis might probably be avoided by the previous injection of dilute solution of antitoxin, and an anti-anaphylaxis thus produced. The blood pressure could be used as an indication of the amount of serum to be injected intrathecally. If there was a fall of blood pressure in an average adult of 40 mm. of Hg the limit of dosage had been reached.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Cure of Squint.

A MEETING of this society was held on Dec. 4th, Mr. **ASLETT BALDWIN**, the President, being in the chair.

Mr. **N. BISHOP HARMAN** read a paper on the Cure of Squint. Squint was the loss of the finest function of the human eyes—binocular vision. Confining his attention to fixed squints in children, he said that in a school of 1000 children no less than 18 were squinters, and that girls were nearly twice as much affected as boys. In 1400 children seen at a children clinic on account of poor vision 199 were squinters. The incidence in these cases was from 100 in the years 4 and 5, to 5 in the fourteenth year. Of these 199 cases 166 were fixed convergent squints, 16 alternating convergent, 8 divergent, and the rest were associated with disease of the eyes. After quoting from ancient authors to show that squint was held to have an evil moral significance, he proceeded to trace the evolution of the binocular vision, and the profound effect it had had on the form of man; he maintained that the upright position and "his fair large front" were directly associated with the evolution of vision. The effect on the brain was similar, for the area of visual cortex was incomparably greater in the hunting animals than in the hunted, and greatest of all in man. The control of the eyes he likened to that of the driver of a four-in-hand. A good driver would master a poor team, but the best team was defective without a driver. So the balance of the eyes was maintained by the fusion faculty of the brain; if that were poor then squint would ensue, even though the eyes were good. Defects of the eyes were adjuvant factors. In not a few cases there was a strongly hereditary tendency to squint. Treatment could be put into three grades. 1. Balancing the vision of the eyes. First there must be correction of any error of refraction by retinoscopy, next exercise of the vision of the squinting eye. 2. The awakening of the fusion faculty. This had been first attempted by Erasmus Darwin in 1778, and modern practice was of the utmost value in ascertaining the power of the brain to resume control under favourable condition. 3. Operation. The rationale of this step lay in the fact that squint of any duration was associated with changes in the tendons, and that these acted as insuperable obstacles to the resumption of brain control. In convergent squint the internus tendon was shortened and thickened, the externus thinned and lengthened. If a true cure was to be effected—i.e., the restoration of binocular vision—then if Stages 1 and 2 of the treatment failed to effect a speedy cure operation should be done before time had stereotyped the vicious effects of the squint. If that time had passed then they were no more than beauty doctors intent on removing an ugly cast. The advocate of early and regular operation must be prepared to present an operative procedure which was both expeditious and reliable. And in this connexion Mr. Harman showed photographs of the steps of his combined operation for lengthening the contracted tendon and shortening the stretched tendon. He maintained that effects could only be secure when both the affected tendons were adjusted; indeed, it was the only method whereby the full mobility of the eye could be secured without subsequent deformity. His operation for shortening a tendon, "subconjunctival reefing and advancement," was performed as follows. The tendon was not cut or exposed to view. The upper and lower edges were cleared by two buttonholes cut through the conjunctiva and capsule. The tendon was freshened by a rasp. Special forceps of simple design were then passed into the buttonholes to secure the tendon. The movement of the forceps folded the tendon. The reef was sewn up or advanced as the case indicated, and then the antagonist was lengthened by a graduated partial tenotomy. The steps of the reefing advancement were as follows: (1) The eye was secured with an anchor stitch placed at the limbus in the axis of the tendon to be shortened; (2) the position of the tendon was noted—it was pointed out that there were well-defined surface markings and colour differences; (3) the buttonholes were cut above and below the tendon close to the canthus; (4) the tendon was lifted and both surfaces rasped with the instrument provided; (5) reefing forceps were applied, adjusted to the extent of the shortening required, and rotated; (6) the reef was sewn up by a double over-and-over stitch; and (7) the reef was advanced by fixing the stitches into the limbus. Then the antagonist was lengthened by the "jigsaw" operation. The tendon was exposed, secured in "director-forceps" which checked bleeding and gave a guide to the incisions. Three cuts were made—athwart the tendon, the middle extending two-thirds from one edge, and the lateral each one-half across from the other edge. The tendon thereon extended lengthwise without loosing its attachments or alignment. Mr. Harman showed how the cuts could be varied to secure vertical deviation also. Results: Of the first 100 serial cases, including the early experimental operations, the results obtained after the average interval of nine months were: Binocular vision, 4; straight, 36; error less than 3°, 22; less than 5°, 23 (these make 85 per cent. successes); error 10° (since corrected), 9; over that, 4; relapsed six months after operation during severe keratitis, 1; and over-correction found six months after operation, 1. He had now almost completed the second hundred cases, and the percentages of successes were still higher. One of the advantages of this combined operation was the power for nice regulation of effects. This was of the utmost importance when operation had to be done early to save the binocular vision, for at an early age a general anæsthetic was commonly needed, and the operator was entirely dependent on his own judgment and technique.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Treatment of Perforating Gastric and Duodenal Ulcers.—Exhibition of Cases.—Intestinal Stasis.

A MEETING of this section was held on Nov. 13th, Dr. F. CONWAY DWYER, the President, being in the chair.

The PRESIDENT read an address on the Treatment of Perforating Gastric and Duodenal Ulcers. For many years he had given up lavage, which he believed to be extremely harmful and responsible for many untoward results. He removed the septic fluid with large swabs and relied on pelvic drains for getting rid of any fluid left behind. Formerly he was of opinion that gastro-enterostomy should be done if the patient's condition permitted it, but in the 12 cases he described he had performed it only in one instance, and then only because the perforation was so large and the edges so friable that when the rent was sewn up he feared the lumen of the bowel was too much narrowed. Eight of the 12 cases made a complete recovery, three did not survive operation more than a few days, and one died a fortnight after operation from pneumonia.

Mr. H. STOKES showed a case of Regeneration of Ruptured Sciatic Nerve. The case was one of arthritis of the hip-joint accompanied by intense pain. Operation was performed for excision of the hip-joint, in the course of which the sciatic nerve was accidentally ruptured. The injury to the nerve was not discovered for two or three weeks. Two and a half years had elapsed since the operation, and the patient was shown to demonstrate the amount of regeneration that had taken place. The suturing of the nerve was done about three weeks after the excision. The small loss of sensation now present in the case was remarkable.—The PRESIDENT considered the absence of wasting in the limb astonishing.

Mr. W. C. STEVENSON showed cases treated by Radium Emanation Needles. From the first patient a malignant polypus was removed by Mr. Graham in May last. It subsequently grew again, and the whole of the anterior wall of the antrum had to be removed, but again the tumour began to grow. The patient came under Mr. Stevenson's care in the end of June with a large gland on one side and a smaller one on the other, accompanied by considerable proptosis. He inserted six needles into the gland, and two or three days afterwards six more needles were put in, and left in for 24 hours. After six weeks the tumour got smaller and redder. When the needles had been inserted four times the tumour showed considerable diminution. A recurrence of the swelling having taken place six weeks after the first application further needles were applied, and the patient showed the effects of the radiation. He had put on a considerable amount of weight. Although he had to take hypnotics regularly before, since the radiation was started he was able to get on without them. Another patient shown had been pronounced by Professor McWeeney to be suffering from epithelioma of the palate. The condition seemed to be much improved, and the ulcer now seen was only about half its original size.—The PRESIDENT said that he had no experience of the application of radium except what he had gained from a short visit to the Middlesex Hospital, where Sir Alfred Pearce Gould had under treatment a large number of cases. In some of them what would seem to have been an almost miraculous cure was brought about. Sir A. Pearce Gould informed him, however, that some of the cases disimproved with extreme rapidity after radium, and that it was wholly impossible to say whether in any particular case a cure would be brought about or whether the patient would be made worse.

Mr. A. J. M. BLAYNEY read a paper on Intestinal Stasis, but the discussion on it was postponed to the next meeting of the section.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held at the Metropolitan Hospital on Dec. 4th, Dr. David Ross, a past President, being in the chair.—Dr. Anthony Feiling read a paper on Acute Paraplegia, of which the following is an abstract. The question of prognosis must always be important in acute paraplegia, or paralysis of the lower limbs of rapid onset. Accurate diagnosis is essential before any prognosis could be given. Hence a knowledge of the various pathological processes which may cause this condition is necessary. These are chiefly three: (1) poliomyelitis; (2) acute myelitis; (3) acute peripheral neuritis or toxic polyneuritis. Poliomyelitis is, of course, identical with infantile paralysis, and is an acute inflammatory disease of the central nervous system; the spinal cord, however, suffered most frequently and most severely. The majority of cases of acute myelitis are in reality syphilitic in origin, the pathological process being a double one, a gummatous meningitis and a softening of the cord following thrombosis of the vessels from endarteritis. The introduction of the Wassermann reaction and the characteristic changes in the cerebro-spinal fluid have confirmed the opinion previously held as to the syphilitic origin of the majority of these cases. The pathology of toxic polyneuritis is less certainly understood; alcohol is very often the etiological factor. The clinical features of these three conditions are often characteristic. The patient's age is an important point of distinction. In poliomyelitis the characteristic features are a day or two of constitutional disturbance, followed by the abrupt onset of paralysis; pain was often a marked feature; objective sensory loss was very rare, and the sphincters were not affected; hypotonia was a prominent feature of the paralysis. The residual paralysis is always less extensive than that present at the beginning of the disease. The patient with acute syphilitic myelitis is generally older. After a few days, in which prodromal symptoms, such as tingling and numbness, may be felt, the paralysis sets in rapidly, and in the course of a few days is usually complete. At first flaccid, it later becomes spastic with exaggeration of the deep reflexes and extensor plantar responses. Loss of sensation is marked and often complete up to a definite segmental level, affording a great contrast to poliomyelitis; it may be of the type known as dissociated anæsthesia. The sphincters are invariably affected, the commonest condition being retention of urine with overflow and obstinate constipation. The final result is a spastic weakness even when considerable recovery had occurred following adequate treatment. In toxic polyneuritis the following points were, said Dr. Feiling, useful in diagnosis: (1) Sensory symptoms are usually most marked; (2) motor paralysis is usually less complete and tended to involve the distal parts of the extremities more than the proximal; (3) the anæsthesia is not segmental in type, and like the motor paralysis involved chiefly the distal parts of the limbs; (4) hyperæsthesia is often a marked feature especially in the alcoholic cases; (5) the sphincters are not affected; (6) rapid muscular atrophy with electrical changes in the muscles supervenes; and (7) there is of course no change to a spastic type of paralysis. The author passed over such cases as the paraplegia of Pott's disease, meningitis, and spinal tumours. Two diseases, he said, had yet to be mentioned in which a sudden paraplegia may occur. These were tabes dorsalis and disseminated sclerosis. In the tabetic cases the paraplegia was usually temporary, and a diagnosis could only be reached by careful consideration of the symptoms, especially pupillary changes. In disseminated sclerosis it would sometimes happen that the further course of the case with its characteristic remissions would provide the only clue. The paper was illustrated by microphotographs and specimens illustrating the pathological lesions of poliomyelitis, tabes dorsalis, and disseminated sclerosis.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 26th, Mr. J. Jackson Clarke, the President, being in the chair.—Dr. H. Crichton Miller opened a discussion on Drug-habit and its Treatment by Modern Methods. He said that the treatment consisted of two stages: (1) the withdrawal of the drug, which could be carried out largely on group lines; and (2) the "cure proper," or a reconstruction of the patient's whole mental and nervous dispositions on natural lines. The latter could only follow strictly individual indications. Having spoken of the causes and of the procedures which are employed in the withdrawal of drugs he considered the "cure proper." This was closely related to the etiology. He spoke of the rôles played by psycho-analysis and hypnotic suggestion in this part of the treatment.—Dr. J. F. Woods recounted his experiences of the treatment of 25 cases of drug-habit.—Mr. Campbell Williams, Dr. R. H. Cole, Mr. Ernest Clarke, Dr. W. H. Willcox, and Dr. J. A. Davidson also took part in the discussion.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the Medical Institute, Belfast, on Nov. 26th, Dr. J. S. Morrow, the President, being in the chair.—Dr. W. Calwell showed several cases, chiefly of dermatological interest.—Dr. H. L. McKisack exhibited a case of Acromegaly.—Mr. A. B. Mitchell showed a case of Solid Œdema of the Face, a case of Ichthyosis, and an Excised Gall-bladder with a large number of gall-stones.—Dr. T. S. Kirk showed a specimen from a case of Ulcerative Colitis treated by excision.—Mr. A. Fullerton exhibited a case of Skin Grafting of Upper Eyelid and a case of Club Foot treated by tarsectomy.—Dr. T. Houston exhibited a series of cases of Acne, showing the results of treatment by vaccines.—Dr. J. C. Rankin showed a series of cases of Lupus Vulgaris, a series of cases of Rodent Ulcer which exhibited Lenthal Cheatle's distribution, and also a case of Lupus Erythematosus.—Mr. Howard Stevenson showed a case of Bone Transplantation after removal of sarcoma of the femur.—Dr. T. Killen showed a specimen of Calcified Hydrocele of the Tunica Vaginalis Testis, and also a specimen of Meningocele successfully removed from a child aged 3 weeks.

MR. W. W. Coltart, L.R.C.P. Lond., M.R.C.S. Eng., having resigned the position of medical officer to Epsom College, which he has held for 28 years, the council has appointed as his successor Mr. P. Jenner Verrall, M.B., B.C. Cantab., F.R.C.S. Eng.

Reviews and Notices of Books.

Lumley's Public Health Acts.

Eighth edition, in two volumes. Edited by ALEXANDER MACMORRAN, M.A., K.C., and JOSHUA SCHOLEFIELD, Barrister-at-Law, assisted by GERARD R. HILL, Barrister-at-Law, and KENNETH M. MACMORRAN, Barrister-at-Law. London: Butterworth and Co. and Shaw and Sons. 1914. Pp., Vol. I., ccclxx., 1205, and (Index) 232; Vol. II., ix., 1392, and (index) 232. Price £3 15*s*. net.

FORTUNATELY for those whose duties render necessary the inclusion in their libraries of the latest edition of "Lumley's Public Health" this valuable and scholarly text-book is not republished frequently. The seventh edition came out in 1908, and in the six years which have intervened about 20 Acts of Parliament requiring some kind of notice in such a work have been passed. These include at least one of importance, the Housing and Town Planning Act, 1909, which is fully set out and occupies 30 pages. Others, such as the National Insurance Act, if not directly concerned with the public health contain sections under which sanitary authorities are affected, which are more or less briefly noted.

The great difficulty in such a compilation is the avoiding of unwieldiness, which in the matter of mere physical dimensions can hardly be escaped from. The cases decided under the Public Health Act, 1875, together with its sections, which of course are set out in full, have brought the number of pages required for adequate dealing with the one statute, the principal one, up to 700, and it is not surprising that the growing bulk of the two volumes, for which four members of the Bar are now responsible, should have caused them some anxiety. In the circumstances, they assure us they have made every effort to secure brevity so far as this is possible without leading to obscurity or omitting details which those using such a book ought to have at their disposal. It is satisfactory to find that some curtailment has been achieved and that it has been effected by shortening the references to cases in the notes, and other expedients explained in the preface, and not by abridgment of the statement of the facts upon which decisions cited are based or of the decisions themselves. This is of obvious importance in the case of a work which, as the editors justly claim, is often used in places where law reports are not easily procurable, "use" in this connexion implying, as they might have added, not merely consultation by those investigating the law upon a particular point for their own guidance, but citation and acceptance in courts of law.

It is hardly necessary to say that medical officers serving local authorities in the great and general movement developed in recent years for the protection of the public health have had to become lawyers with a corresponding abandonment of their functions as medical practitioners. Further, a working knowledge of the special branch of the law which concerns them is essential to the proper fulfilment of their duties, and their influence for good must largely depend upon their appreciation of their own powers and limitations, and of the powers of the sanitary authorities whose guides and counsellors as well as servants they are. Such a working knowledge of public health law will certainly be his who, having obtained intimacy through practical experience with the Acts and regulations applying to his routine duties, has learned to "know his way about" in "Lumley's Public Health." In doing this he will, however, be aided by a copious and well-arranged index, conveniently repeated in each volume, by a table of statutes, and a table of contents and table of cases, the fulness and careful arrangement of these guides to the searcher leaving nothing to be desired. It cannot be too often impressed upon compilers of legal text-books, and particularly of those which are for the guidance of lay officials in their duties, that it is not merely the matter which they include in a weighty volume, but the degree in which they render it accessible, which will win the appreciation of their readers.

The eighth edition of "Lumley's Public Health" will no doubt command the appreciation which the usefulness of its predecessors will have helped to win for it. Its purchase by local sanitary authorities for the benefit of those in their jurisdictions and for the use of their officers is therefore to be recommended, as its cost without being prohibitive or excessive in view of the value of the book itself, might be a heavy charge for the individual pocket.

Chemistry and its Borderland.

By ALFRED W. STEWART, D.Sc., Lecturer on Organic Chemistry in the Queen's University of Belfast. With 11 illustrations and 2 plates. London: Longmans, Green, and Co. 1914. Pp. 314. Price 5*s.* net.

THE purpose of this book is admirable, and in our view the author has succeeded in presenting "an account of some recent developments in chemistry couched in language which need not present any impediment." He realises that an interest in the progress of scientific investigation is more and more manifest, and that on all sides an intelligent curiosity is springing up as to the meaning of recent advances in science. Chemistry in its application to industrial operations is not easily explained to the ordinary man, and the chemist often resorts to a symbolic language which is unintelligible except to the initiated. The author takes the position that works on chemistry designed for the general public are apt to err either in being too elementary in treatment or in taking too much knowledge for granted on the part of the reader. We agree; and we are glad to find that in his lucid account of the subject no chemical symbols have been introduced, while elementary truths have not been laboured. The result is a readable and interesting account of the bearing of chemical developments on modern life.

Amongst other things the author brings forward the fact, which is not very generally appreciated, that all the applications of science which render our life more endurable have had their beginnings in the workshop of researchers who were striving after knowledge for its own sake. He draws attention to a few well-known instances in modern chemical research, in which the first efforts seemed to be of merely academic interest, but which have proved the foundations of far-extending industries, providing employment for thousands of men. We have not read a clearer or more interesting account of chemistry in its relations to daily life and modern needs. The chapter on immuno-chemistry, even with the words he is bound to use—like haptophore, toxophore, receptor, and so on—serves as a very good example of the author's clear exposition and writing, and should free this complicated subject from the ambiguities which may exist in the minds of many readers. The chapters on colloids and the ultra-microscope, chemistry and industry, the inert gases, chemistry in space, and transmutation, are equally good and attractive, but the book is at its best, we think, on the vital questions of food and power in the future and in its treatment of the chemical problems of now and afterwards.

Syphilology and Venereal Disease.

By C. F. MARSHALL, M.D., M.Sc. Vict., F.R.C.S. Eng., Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars; formerly Resident Medical Officer to the London Lock Hospital. Third edition. London: Baillière, Tindall, and Cox. 1914. Pp. 465. Price 10*s.* 6*d.* net.

THIS work has reached a third edition in a few years, and we are not surprised that it has been received with favour by the profession, for it contains a clear, careful, and complete account of syphilis and the other venereal diseases. About three-fourths of the book are devoted to syphilis, and it is evident that the subject has been fully thought out. Each chapter contains a very useful list of references to original authorities.

The section dealing with the treatment of syphilis is especially good, and the author adopts a wise position as to the relative values of mercury and salvarsan. The chapters on chancroid and on gonorrhœa are good, and there is a section dealing with venereal disease and public health which deserves special mention. A very important part of this chapter relates to syphilis in connexion with life assurance, and it should prove of value to junior life assurance officers.

Festschrift Herrn Dr. H. Bircher,

Direktor der Kantonalen Krankenanstalt, Aarau (Schweiz), und Chefarzt der Chirurgischen Abteilung, zu seiner 25-Jahrigen Amtstätigkeit, überreicht von Freunden und ehemaligen Assistenten 1887–1912. Tübingen: H. Laupp. 1914. Pp. 523. With 1 portrait, 129 figures, 1 chart, and 1 curve. Price 18 marks.

Dr. Heinrich Bircher has been a man of many activities in Aargau for the last quarter of a century, we read in a dedicatory address at the beginning of this *Festschrift*, and has been the source of the inspiration resulting in the 20 papers that compose it. His portrait shows the face of a masterful man, not unlike that of the Member for Waterford.

In the Aargau district of Switzerland there is a great deal of goitre, and during Dr. Bircher's 25 years 1529 operations on the thyroid gland have been performed, 1425 in benign goitres, 56 on malignant goitres—carcinoma or sarcoma—and 48 upon goitres showing signs of inflammation. Over two-thirds of the benign goitres occurred in women; in all cases a general anæsthetic was employed, and post-operative fever, occurring in half the patients operated upon in 1890, was seen in but 16 per cent. of the cases in 1911. The recurrent nerve was injured in 2½ per cent. of the operations, and the operations proved fatal in 2¼ per cent. of the cases. About 300 pages of the *Festschrift* are devoted to various aspects of the goitre problem, and the four papers in which they are considered are worthy of a careful study. Dr. E. Bircher, in a general account of goitre, comes to the conclusion that the enlarged thyroid gland must produce a special toxin that is responsible for the more or less serious cardiac troubles ("Kropfherz," goitre-heart) that occur so frequently in these patients, and brings forward arguments to prove that the disease is due to a colloid toxin occurring in many Swiss drinking waters. W. Bigler, in a paper on the Cardiac Lesions of Goitrous Patients, says that his material includes about 150 cases, 100 of them carefully observed; in 50 patients with tracheal stenosis due to the enlargement of the thyroid, 23 only showed cardiac hypertrophy, so that mechanical causes can hardly underlie the enlargement of the heart. He found that no histological type of goirte was constantly associated with the cardiac disturbance, and does not think that any quantitative upset of the secretory activity of the thyroid gland will account for it; in fact, he leaves the connexion between goitre and goitre-heart unexplained.

Many other of the 20 papers composing the *Festschrift* are excellent pieces of work, and the whole volume affords abundant evidence of the vitality of surgery, medicine, and pathology in Switzerland.

LIBRARY TABLE.

Cane Sugar and Heart Disease. By ARTHUR GOULSTON, M.A., M.D. Cantab. London: Baillière, Tindall, and Cox. 1914. Pp. 107. Price 5*s.* net.—Having in view the use of sugar in the German army and among Alpine climbers to sustain them under severe cardiac strain, the author was induced to try the effect of pure cane sugar in the treatment of various kinds of heart disease which failed to respond to ordinary treatment. His first case was that of an enfeebled lady, 74 years of age, who suffered from fluttering heart, with rapid, irregular, and intermittent pulse. Under the cane sugar treatment she gained strength and vigour, and ten years later is quite well, walks out daily, and travels alone. The author discusses the subject of heart failure, the physiology of cane sugar in relation to heart muscle, and gives the details of his method of treatment, which consists in the administration of 2 oz. of pure cane sugar daily for the first week, 3 oz. for the second week, and 4 oz. from then on as long as required. Total abstinence from alcohol and tobacco is enjoined, diuretics are given if required, and rest and plain diet enforced. The class of cases in which he claims to have seen almost constant benefit includes auricular fluttering and pseudo-angina pectoris due thereto, auricular tachycardia, valvular lesions after acute rheumatism, and tobacco heart. He records 20 representative cases with a few illustrative tracings. The cases are carefully taken clinical records, not always by himself. The book is suggestive, but the cases are hardly sufficient in number to justify any general conclusions or wide claims.

The Progress of Scientific Chemistry in Our Own Times. By Sir WILLIAM A. TILDEN, D.Sc., F.R.S. Second edition. London: Longmans, Green, and Co. Pp. 366. Price 7*s.* 6*d.* net.—The first edition of this interesting, though small, volume appeared in 1899, and we are glad it has now been succeeded by a second edition bringing the subject matter to date. We are not aware that a clearer or more concise account exists of the successive steps which have led to the system of theory generally accepted by chemists at the present day. Professor Tilden has done wisely also to add to each chapter a series of biographical notes of the great founders of chemical science. These notes are naturally placed at the end of the chapter in which their work of laying foundations is described. In this way the connexion between discovery and general progress is usefully brought out. The story is told in simple terms, and it presents a most interesting record of chemical science.

Pathologie Interne et Diagnostic. By ROGER HYVERT. Second edition. Paris: A. Maloine. 1914. Pp. 510. Price 6 francs.—This compact work, which forms one of the series of guides to practical medicine, having been favourably received in its first edition, is now put forth as a second edition which has been entirely revised. The author has arranged the various symptoms and diseases in alphabetical order, and under each heading has given a succinct account of the condition. The book may indeed be described as a dictionary of medicine, and in the small space at his disposal the author has collected much information which will serve as a compendium for immediate reference by the busy practitioner. A useful feature is the tabulation in the index of the various reactions, signs, and syndromes, alphabetically under the names of the various observers who first described them and after whom they are now known.

The Sanitary Inspector's Handbook. By ALBERT TAYLOR, Sanitary Inspector, City of Westminster. Fifth edition, with illustrations. London: H. K. Lewis. 1914. Pp. 612. Price 6*s.* net.—Now that this book has been brought up to date, with references to recent new regulations in sanitary administration, it again forms, as previous editions did, a very useful guide to the sanitary inspector. He will appreciate mostly, we think, the clear statements given as to his duties and the requirements in regard to them. The chapters on house drainage, drain testing, baths, sinks, and water-supply are particularly good, and the chapter on infectious diseases and disinfection is extensive and practical. The author displays a wide experience of the work that falls to a sanitary inspector.

German Technical Words and Phrases. An English-German and German-English Dictionary. By C. A. THIMM and W. VON KNOBLAUCH. Second edition, revised and enlarged. London: E. Marlborough and Co. Pp. 241. Price 2*s.* 6*d.*—The preface to this edition states that the dictionary is not intended to compete in any sense with the literary and commercial German dictionaries in the market. It is distinguished from these in supplying professional and business men with words, terms, and phrases peculiar to their respective callings and occupations, and necessarily of a scientific or technical character. A supplemental list of 20 pages has been added to this edition with cross references where necessary. In this list we observe rugine and scraper both translated as "zahnmeissel." "Zahnputzer" would have been more correct for tooth-scraper or dental rugine. Zahnmeissel, or dental chisel, also conveys the idea of a toothed chisel or toothed-plane-iron used for veneers in cabinet-making. It is easy with the German "Zahn" prefix to confuse "denticulated" with "dental." There are a few other misprints, such as "scoffolding," "steimasse," and "makalatur," but these are not important. Since its size will enable it to be carried in the waistcoat pocket it is a useful little book.

MISCELLANEOUS VOLUMES.

The war is such an all-absorbing topic at the present time that books bearing upon its etiology, symptomatology, and prognosis will have interest for our readers. Yet the selection of the numerous works having their origin in the war which lies before us does not contain any really valuable work.

First by its extensive aims comes the *Diplomatic History of the War*, edited by Mr. M. P. Price (London: George Allen and Unwin, Limited. 1914. Pp. 344 + 102. Price 7*s.* 6*d.* net), and we do not attempt critically to review it. All we shall do is to indicate the task the author has set before himself, and our general opinion as to how far he has succeeded in accomplishing it. He professes, then, to have collected and reproduced the various official documents of the various Governments and the public speeches in the European Parliaments, to which he has added texts of treaties bearing on points of importance and some of the more important press correspondence bearing on the war. From these data he has arranged a chronological diary of events, and has prefaced the whole with a historical introduction purporting to examine why the conflagration has spread from Eastern Europe, and "to uncover the methods by which the diplomacy in the different capitals has worked, leading Europe to the inevitable and disastrous end." He interlards this review with running comments indicating where, in his opinion, blame or praise seems justly to be deserved. We cannot regard the result as satisfactory in this last respect, as there seems to us a too evident bias, due to the author apparently having read his conclusions into the data instead of having drawn them therefrom. As a collection in one volume of much official material for students of the subject it may be useful. The recent publication of the French Yellow Book, however, must materially add to the cumulative weight of the Allies' case.

Of General Friedrich von Bernhardi's book, *Germany and the Next War*, translated by Allen H. Powles (London: Edward Arnold. 1914. Pp. 288. Price 2*s.* net), it is here necessary only to state that it sets forth the doctrines of "Might is right" and "World power or downfall," which have been the predisposing causes of the present war conflagration. We suppose that no one who reads the book can fail to see that with such a viewpoint dominant in any nation that nation must sooner or later find the civilised world in arms against it. Let us hope that if no middle way comes to the surface between the author's alternatives the triumphant one will not be world power.——In *The Kaiser's War* (London: George Allen and Unwin, Limited. 1914. Pp. 251. Price 2*s.* net) Mr. Austin Harrison sets out to expose the entire German philosophy of the war. Starting with the origin of the "world power or downfall" idea, he shows the growth and dominance of the materialistic "might is right" conception, which leaves out of account the moral forces of mankind. The Kaiser's diplomatic mistakes before he embarked on war are noted, and a like number of military mistakes, Mr. Harrison thus essaying to dispose of the Kaiser's claim to the title of a great monarch. Following the methods of criminal investigation, Mr. Harrison next essays to "reconstruct" the German case. A chapter on the collapse of Socialism is intended to show up the falsity in practice of the claims to solidarity and internationalism on the part of Socialism and will not prove in the least convincing. A comparison of the guiding principles and methods of England and Germany closes an interesting book.——Dr. Armagaard Karl Graves, who was sentenced in 1912 to 18 months' imprisonment as a spy, having already been 108 days in custody, lays bare in *The Secrets of the German War Office* (London: T. Werner Laurie, Limited. 1914. Pp. 182. Price 2*s.* net), the inner workings of German secret intelligence methods. The last chapter, Arming for Peace or War—the manuscript of the book, the publishers assure us, was in their hands last June—starts with the assertion that "the map of Europe is certain to undergo some very decided changes within the next decade, very possibly in less time." He sets forth the essential racial distinctions between the three great groups of European nations, the Teutonic, the Latin, and the Slavic, and it is easy to see that to his thinking the odds are in favour of success for the Teutonic race, for which, in addition to the commercial and military pre-eminence of Germany, he seems to rely on two factors: 1. The fact that there is no Catholic ruler in a Catholic country to-day able to support and protect the dignity of the Church, while the German Emperor "is a Protestant monarch, but he is first and last a Christian." 2. That the Scandinavian races trust Germany but not Russia. This is an interesting book, but we have no means of gauging its accuracy.——Mr. J. M. Kennedy's *Nietzsche* (London: T. Werner Laurie, Limited. 1914. Pp. 192. Price 1*s.* net) is an attempt to show, by means of representative quotations from Nietzsche's writings, that those who regard him as the founder from a spiritual, if not from a political, point of view of the new Germany, are greatly in error, and that the idea at present so prevalent in England that the influence of Nietzsche's writings was a dominant factor in producing the present war is entirely baseless. It may be true that Nietzsche "loathed the very name of empire," and that he severely criticised the Germany of his own time, and in even stronger terms the Germany which was developing out of it; but it seems to us that, without going beyond the quotations given by the present author, the doctrines of Treitschke and Bernhardi constitute but a logical application in a contracted sphere of principles which underlie Nietzsche's teaching. Mr. Kennedy lays himself open to criticism when he states in the preface that "the 'Christianity' attacked by Nietzsche in the following pages is 'the lifeless Christianity of the Lutheran Church.'" The statement seems to us entirely disproved by passages about the New Testament quoted on p. 185 of the work. The book is far from convincing.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Meeting of Comitia.

A Comitia was held on Dec. 3rd, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair.

The following communications were received:—1. From the secretary of the Royal College of Surgeons of England, dated Nov. 12th and 13th, reporting proceedings of the Council of that College on Nov. 12th. 2. From the Foreign Office, dated Nov. 4th, thanking the College for their communication concerning the sale of narcotic drugs.

Sir Dyce Duckworth, the treasurer, announced that the Finance Committee had recommended that the sum of 50 guineas should be presented to the Belgian Doctors' and Pharmacists' Relief Fund.—The recommendation was adopted.

Dr. J. E. Squire presented to the College two old clinical thermometers in use up to 1870, which had belonged to his father, Dr. William Squire.—The thanks of the College were returned to Dr. J. E. Squire for the gift.

Dr. Newton Pitt was elected a Censor in the place of Sir Wilmot Herringham, M.D., resigned.

Dr. A. E. Ormerod, the Registrar, presented for approval of the College certain new regulations for the award of the Weber-Parkes prize. Hitherto the prize had been awarded triennially to the writer of the best essay upon some determined subject connected with the etiology, prevention, pathology, or treatment of tuberculosis. A silver medal had been awarded to the holder of the prize, and a similar medal, distinguished as the second medal, to the essayist who came next in order of merit. According to the new regulations, which were adopted by the College, the prize would be awarded triennially for the best work already done in connexion with the etiology, prevention, pathology, or treatment of tuberculosis; a silver medal would still be awarded to the holder of the prize, but the "second medal" would be discontinued.

A report was received and adopted from the Committee of Management, dated Nov. 17th. The report recommended that the Newcastle-on-Tyne Royal Grammar School should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

The President then dissolved the Comitia.

THE LANCET.

LONDON: SATURDAY, DECEMBER 12, 1914.

Medical Certification under the National Health Insurance Act.

THE National Health Insurance Commissioners for England, Scotland, and Wales have decided to bring into operation a new system of medical certification, and have issued to all concerned a Memorandum explanatory of the procedure to be adopted. The Commissioners, we may be certain have known for some time of the difficulties; they have arisen in the working of the Act out of the absence of uniformity in the method of giving certificates, and have often been alluded to in our columns. Faulty systems adopted by the administration of various Approved Societies have played their part in these difficulties, but must not be regarded as alone responsible for them. They have been also brought about by the embarrassment of medical men, whose professional education, though highly standardised in the direction of the prevention and treatment of disease, had been neglected (and surely naturally) in directions where the filling up of forms plays so important a part. The demands of the officials of some societies in respect of certificates have been unjustifiable, but at the same time we do not deny that there has been a laxity of procedure on the part of certain members of the medical profession; it is to meet the unsatisfactory position which all allow has existed from the earliest working of the Act that the National Health Insurance Commissioners have framed a new scheme of procedure. The scheme applies to all cases in which insured persons need medical certificates of incapacity for work, in support of claims either for sickness or disablement benefit, or, indeed, for any purpose under the Act; although, for the sake of brevity, the term "Sickness Benefit" is used throughout the Memorandum.

The scheme will come into operation on Jan. 1st, 1915, and has two objects. The first, as will be gathered by what we have said, is to secure the necessary measure of uniformity of procedure on the part of Approved Societies, insured persons, and practitioners in respect of those matters which can satisfactorily be made subject to definite rules; the second is to bring about a general understanding amongst all concerned as to the procedure to be followed in various exceptional contingencies which cannot satisfactorily be dealt with under formal rules. The first object is immediately achieved. Uniformity will be secured by the fact that every medical certificate of incapacity of insured persons for work must be given on a form determined by the Commissioners. The forms will be issued to practitioners through the Insurance Committees in compact books, and the notice of sickness required by the Approved Societies showing declaration of the incapacity, claim for benefit, and declaration "off" benefit, are printed on the same form as the medical certificate, a procedure which manifestly makes for simplicity and economy of labour. Every certificate will bear the date of signature, which will normally be the date on which the doctor made the examination of his patient, and the times of giving certificates are to be governed mainly by the arrangements which the practitioner makes for seeing the patient in the ordinary course, "and will bear no necessary relation to any system adopted by the insured person's society of paying benefit on some particular day of the week." We quote here the words of a wise provision in the Memorandum. It is one which the Approved Societies can without much difficulty to themselves make arrangements to meet, while it will remove considerable trouble from practitioners who have hitherto been pressed to sign certain documents by certain dates, and will relieve the insured persons from anxiety as to the fairness of any time arrangements under which their benefits are received. The uniform medical certificate includes a description of the cause of incapacity, and the practitioner is required to certify not only as to whether the insured person is incapable of work, but also as to the specific disease or bodily or mental disablement which is the cause of the incapacity. One of the Rules which have been settled by the Commissioners for the giving of medical certificates, and which are appended to the Memorandum, deals adroitly with a difficult point in this connexion. It is obvious that the exact cause of incapacity ought sometimes to remain a matter of confidence between the patient and his medical man, and this point of view is strongly supported by the whole medical profession. The Rule in question provides that "in any case where a precise statement would in the practitioner's opinion be prejudicial to the health of the patient, or where it would inflict on him unwarrantable injury, the practitioner may describe the incapacity, disease, or disablement in less precise terms." In these cases the practitioner is required to send, on the day on which the certificate is signed, to the Approved Society of which the insured person is a member, an additional notice declaring that he has stated the cause of incapacity in his certificate with less precision than his present knowledge warrants, for good and sufficient reasons which he has communicated to either the Government referee appointed for the purpose, or, where no such referee has been appointed, to the Commissioners themselves. The practitioner of course will send also to one of the indicated authorities the precise description alluded to in his declaration. The Rule has been carefully designed to meet a situation where public policy and professional right feeling have been at variance, and we think that working under it should be smooth in the future.

The procedure to be adopted with regard to second, intermediate, and final certificates is carefully explained in the Memorandum. The practitioner is required to give the second certificate, if so desired by the insured person, within eight days of the first certificate, when, if he is satisfied that the patient, although incapable of work up to that date, is fit to resume immediately after, his second certificate will take the form of a final certificate. Otherwise further certificates are to be given from week to week during the period of incapacity. The final certificate must be given by the practitioner, whether asked for by the insured person or not, directly the conclusion is reached that the patient is fit to resume work immediately after the date of the examination, and to this certificate the insured person must add on the same form his declaration off the funds of the Approved Society for delivery to that body. The difficulties to which medical practitioners have drawn attention as affecting the giving of final certificates are well summarised in the Memorandum. They arise in respect of persons who are found on examination to be found not quite fit for work, but likely to be fit within a few days. In the absence of precaution the patient may not see the practitioner until some days after he has become fit for work. The medical man will not then be able to certify personally as to the day on which the patient became capable of work; and the insured person will not be able to obtain a final certificate, since the latter, in the form now required, is not only a certificate of fitness to resume work after the date of examination, but also a certificate that the patient has, in medical opinion, been incapable of work up to and including that date. To meet this situation the practitioner is required to insert in the proper space on the first and intermediate certificates the date on which the patient should pay a further visit, if at the time of giving the certificate the practitioner is satisfied that the patient, though not fit to resume work immediately, will be fit before a further certificate would next ordinarily be given. Other situations, where the giving of certificates is for one reason or another attended with difficulties, have been amply provided for, and we congratulate the Commissioners on a scheme which has been carefully thought out to meet the troubles which cluster round medical certification.

The Treatment of Tetanus.

AT the meeting of the Medical Society of London on Monday last an interesting discussion was held on the prophylaxis and treatment of tetanus, a subject of great importance at the present time when many wounded soldiers of the Allied Forces in Belgium and France have been suffering from this disease. The debate, which is reported in this issue of THE LANCET, was distinctly a success; every speaker was well acquainted with his subject, and those who were present heard the very latest views of the mode in which tetanus is brought about, and first-hand opinions as to the best way of dealing with it. It was only to be expected in so difficult a subject, and one where practical clinical experience has been on the whole so limited, that these opinions did not always coincide in detail.

The debate was opened by Captain DENNIS EMBLETON, who had had opportunities both at the 3rd London General Hospital and at Netley of observing a series of cases presenting a varied picture of the disease. He dwelt on the improbability of any localisation of the tetanus organism, and considered that carbolic acid, even pure and applied two minutes after the infection had been produced, was ineffective, while by damaging the tissues it might be dangerous. He held that the value of antitetanic serum for prophylactic purposes had been definitely established, and that its administration in established tetanus had been proved experimentally to be of value when the subcutaneous route of administration was the safest. Professor F. W. ANDREWES, who followed Captain EMBLETON, pointed out that it was by no means every wound, exposed to the possibility of infection by tetanus, that was really likely to be infected. The main source of the bacillus is to be found in the intestinal excretions of the ox and also especially of the horse, and therefore the mud of the roads is extensively impregnated with this germ; so, too, all soil that has been treated with stable manure must contain very many of the organisms. Dr. ANDREWES described some experiments performed in this connexion; he had taken some of the earth from his garden and had inoculated a number of mice with minute portions of it, and though in some of the cases the amount of soil used was extremely small, yet every single mouse had become affected with tetanus. However, though garden soil teems with this bacillus, it is extremely rare for any gardener to suffer from tetanus, though daily he must have superficial abrasions with which the bacillus must have been smeared. It appeared, then, that superficial lesions were very unlikely to lead to the development of the disease, and this Dr. ANDREWES was inclined to attribute to the fact that the bacillus of tetanus was anaerobic, so that free exposure to the oxygen of the air prevented the development of the organism. This free exposure to the air was, in his opinion, far superior to the employment of hydrogen peroxide or of potassium permanganate. This view did not commend itself to all the speakers, while Captain Embleton had previously laid great stress on the damage of the surrounding tissues as an important factor in the development of the germ, and especially in the associated inoculation of septic organisms.

As to the treatment, all the speakers agreed that the use of antitetanic serum far surpassed other methods that have been devised, and that hypnotic and sedative drugs held a very secondary place in treatment, though they might be useful in relieving pain, in allowing the reception of food, and in inducing sleep. It was also agreed that the serum should if possible be given prophylactically, but at once the difficulty arose that it was practically impossible to administer the serum to every wounded man, for the available stock of serum was utterly insufficient. How, then, can the suitable cases be selected? It seems that deep wounds are more likely to be affected than those which are more superficial, but some further differentiation is necessary, and Dr. Andrewes suggested that the demonstration of the presence of the Gram-positive bacillus of Welch was very suggestive of the presence of the bacillus of tetanus, and so far as he has used this test it appears to be well founded. By some such method the number of cases to which the serum should be given prophylactically may be much reduced. When the dose of serum has been delayed for one cause or another till the symptoms become manifest its value is markedly reduced, but it may be given here with good effect if the dose is greatly increased. The channel of administration has also to be determined. It is curious to note that while one observer favoured the subcutaneous route another considered the intravenous method the best, and a third speaker held that the serum should certainly be injected into the subarachnoid space of the spinal cord; and with this last view we are inclined to agree if a prompt action of the serum be desired. The intracerebral injection found no supporter, though it was admitted that it might be employed in very serious cases as a last resource. The intracranial method must do immense damage to the structures of the brain, unless the quantity of fluid injected be limited to a few drops. It was clear from the whole of this very interesting debate, as well as from the differences of opinion upon the method of administering the accepted remedy, that our knowledge of the therapeusis of tetanus is still in a state of flux. We have in the antitetanic serum an agent of a high degree of potency. Further experience will show us how best it may be used, but at present it is abundantly clear that in its early prophylactic use lies the best hope of combating a deadly disease.

Annotations.

"Ne quid nimis."

UNDERWEAR AND WAR.

The history of underclothing has been neglected, while external costume has been extensively described. Yet underwear, though humble and obscure, has manifestly played an important part in the hygiene of peoples and of armies. Our ancestors were hardy and often cold. Charles I., according to tradition, shivered on the snowy day of his execution (Jan. 30th, 1649), and wore as many shirts as possible next his skin, which seems to prove that the modern vest was then unknown. Drawers, a word of humble origin according to the New English Dictionary, were for ages made of linen or some similar material. Cotgrave, writing in the year 1611, speaks of drawers as short and close breeches or underhose of linen, and in the *Spectator*, No. 51, which was written by Steele, holland drawers are mentioned. The French have an old and well-established word for this article of dress, and in Boyer's French-English Dictionary, edition 6, 1738, we find "*caleçons*" duly referred to and explained by the customary English translation, but these garments must have been short in an age that wore breeches and that prided itself on the contours of what was known as "a leg." In Bailey's Dictionary (1737 edit.) the valuable garment is not referred to, and those who closely examine Hogarth's pictures, such as the "Orgie in the Rose Tavern," will find that it is not worn by the dishevelled beaux and others there depicted. Woollen underclothing dates in England from the second half of the nineteenth century. At first it was regarded as a fad, and is so regarded by the French and Italians to-day. *Caleçons* in France and in Italy are still made of cotton, and are quaint trouser-like garments. An old-fashioned Frenchman in his underclothing presented a curious spectacle. There were so many buttons about him. One such, and as lately as 1890, has described the revolution caused among Frenchmen by the introduction of cotton underwear from England in the time of Louis Philippe or earlier. The English culture-drift, he averred, gave his section of Protestant France, drawers, pietism of the school of Mrs. Fry, and steel pens. He adopted the first and last, and rejected the central product of a leading civilisation. The French are still all for cotton. A young French officer now lying wounded in Le Havre, and loud in his praise of the English Red Cross and the English Tommy, assures us that in his circle the wearing of wool next the skin is regarded as "*vieux monsieur*," or, as we should say, "mollycoddling." We wonder if our gallant allies are properly clothing themselves in their present terrible circumstances. If they are wearing wool next the skin they have passed through yet another revolution, none the less drastic because unseen or obscure. Our own soldiers, on the other hand, are probably better clad, thanks to our knitters, and fed than in any previous campaign. So ineradicable in itself, custom in food and dress has more to do with the hygiene and *moral* of a winter campaign than many suppose.

EPSOM COLLEGE.

WE publish this week a letter from Sir Henry Morris, in which he calls the attention of our readers to the close link between Epsom College and the medical profession. Old Epsomians and others who have identified themselves with the fortunes of the College are not likely to need this reminder; but there must still be many who are unfamiliar with the advantages offered by Epsom College as a school for the sons of medical men, and with the claims of the Royal Medical Foundation of Epsom College upon the generosity of the medical profession and its friends. Owing to the war, which has complicated everything so that scarcely a single wheel of life now revolves at the old rate, money is increasingly difficult to raise for what may be called the peaceable charities. Nevertheless, the Council looks to the friends of Epsom College to bear the needs of the Royal Medical Foundation in mind, so that as the older supporters drop out one by one their places may be filled up and the excellent work of the institution may be carried on with undiminished success.

WHOOPING-COUGH IN NEW YORK.

IN New York City whooping-cough is known to cause three or four hundred deaths per annum, more than half of the victims being infants under one year of age. The director of the City Bureau of Infectious Diseases has determined to cut down this loss of life, if it can be done, by the employment of the following measures.[1] As whooping-cough is infectious for a week or more before the appearance of the characteristic whoop makes it diagnosable, to prevent the spread of infection at the outset is impossible. The Department of Health therefore proposes to concentrate its efforts on protecting infants and very young children from infection with the disease, and on furnishing suitable care for such of them as may contract it. Arrangements have been made to admit certain cases into hospital, where they will be kept until the period of maximum infectivity is over. Other cases will spend the day in "day-camps"; it is hoped that a disused ferry-boat will be available for use as a whooping-cough day-camp, moored close to a children's hospital that will serve as its base of supply. Yet other cases will attend at special whooping-cough dispensaries. In addition, district nurses will devote a large amount of their time to visiting the homes of infected children, advising and educating the parents in the management of the cases and the best methods of avoiding the spread of infection. Whooping-cough is a notifiable disease in New York City, but the notification is made in a very perfunctory spirit, it seems; thus out of 116 institutions, hospitals, and dispensaries caring for cases of whooping-cough, 49 were found not to be in the habit of notifying them to the Department of Health as required by the Sanitary Code. The control of whooping-cough is very much hampered by the incompleteness of our knowledge of the exact cause of the disease. It has not been proved that the same micro-organism is present in every case of pertussis. Most observers have found the minute bacillus described by Bordet and Gengou in 1906, faintly staining, Gram-negative, less pleomorphous than the very similar influenza bacillus that is morphologically indistinguishable from it. As the disease advances the Bordet-Gengou microbe may disappear from the sputum, while the whooping persists. Various strains of this bacillus have been isolated from different cases, and this is a factor of the greatest importance in considering the treatment of the disease with vaccines. It appears also that mixed infections are not rare in whooping-cough; for both these reasons the identification of the infecting agent in any particular case by means of complement-fixation tests is unsatisfactory at the present time. Finally, we still lack definite evidence as to the specific pathogenic action of the bacilli in pertussis. Mallory has recently claimed that the specific lesion consists in the presence of the microbes among the cilia of the epithelial cells in the trachea and bronchi; further work, however, is required before the truth of this interesting hypothesis can be admitted. It will be remembered that Bordet insists that there must be in whooping-cough a specific toxin that produces hypersensitiveness of the recurrent laryngeal nerve and its centre. The vaccine treatment of pertussis is said to have proved disappointing, though harmless, in New York, no doubt for the reasons indicated above.

VENTILATION AND HUMIDITY IN TEXTILE MILLS AND FACTORIES.

THE question of the ventilation and humidity in textile mills and factories has for a long time presented considerable difficulty. The chief problem was how the conditions of the atmosphere in the weaving shed could be so adjusted that at the same time they should be favourable to the operation and without prejudice to the health of the worker. It is well known that in the textile industries the dampness of the atmosphere in which manufacturing processes are carried on is of primary importance, and, as is pointed out by Mr. Cecil H. Lander, M.Sc., A.M.I.C.E., A.M.I.M.E., lecturer in civil engineering in the University of Manchester,[1] this was recognised by the early spinners and weavers, inasmuch as hand looms were often installed in a damp portion of the worker's cottage and the earth floor was watered if necessary and wet cloths hung round or near to the warp beam. On the introduction of the spinning-frame and the power-loom, and the consequent grouping of many machines under one roof, the textile industry tended to rapid growth in districts where the natural amount of atmospheric moisture was great. So the development of this industry took place in moist climates such as prevail in Lancashire and in the north of Ireland. Moisture is, in fact, essential in the production of yarn of maximum strength. Official inquiries have been made from time to time as to the effects of high humidity and temperature upon the health of the weaver, and in one report the general emaciated appearance of weavers was observed, and this was attributed "to the effects of the warm moist atmosphere in which weavers work, for they are not seen in outdoor labourers or in workers in other industries in Lancashire." During recent years the matter, as is well known, has received the attention of the Home Office, and the Factory Acts now require that if the wet-bulb temperature in a weaving shed reaches a certain specified maximum all artificial humidification should be cut off. Mr. Lander has given a very interesting account not only of the general questions of ventilation and humidification but also of the methods and appliances introduced to render a compliance with the requirements of the Act possible without interfering with the conditions essential for manipulating and producing a satisfactory yarn.

THE CLASSIFICATION OF TRYPANOSOMES.

IT is generally recognised that the classification of trypanosomes is a very difficult subject, and hitherto all attempts which have been made to deal with the problem have proved unsatisfactory. A fresh endeavour to overcome the difficulty has recently been made by Surgeon-General Sir David Bruce, Director of the Sleeping Sickness Commission. At the October meeting of the Society of Tropical Medicine and Hygiene Sir David Bruce explained his new system of classification of the African trypanosomes pathogenic to man and domestic animals. His method is based on three principal points—namely, the morphology of the trypanosomes, the action of these parasites on animals, and, lastly, the mode of the development of these organisms in the tsetse fly. With the exception of T. evansi and T. equiperdum all these parasites are carried from sick to healthy animals by tsetse flies. On these grounds Sir David Bruce classifies the pathogenic trypanosomes into three separate groups. The first is the T. brucei group, which includes four species—namely, T. brucei, T. gambiense, T. evansi, and T. equiperdum; the second is the T. pecorum group, comprising two species—T. pecorum and T. simiæ; the third is the T. vivax group, including three species—T. vivax, T. capræ, and T. uniforme. These may be said to constitute all the principal important trypanosomes discovered up to the present time in Africa. As regards the development of these organisms in the tsetse fly, in the first group it begins in the gut of the insect and is completed in the salivary glands; in the second the development commences in the gut of the fly and finishes in the proboscis; and in the third group the whole development of the trypanosome takes place solely in the proboscis of the fly. When this new classification came to be discussed by the Society of Tropical Medicine and Hygiene some members criticised it freely, while others admitting the general soundness of the division into three main groups according to the development in the fly, thought the classification was the best from the zoological point of view. No doubt with some revision the system of classification proposed by Sir David Bruce will go a long way towards removing the chaos which has hitherto surrounded this important subject.

Sir Frederic Eve, senior surgeon to the London Hospital, has sent in his resignation as from the beginning of December, when he completed a period of 30 years' service on the surgical staff. The committee unanimously elected him consulting surgeon to the hospital. Sir Frederic Eve has been appointed by the Army Council consulting surgeon to the troops serving in the Eastern Command with rank and pay of lieutenant-colonel.

THE INDIAN MEDICAL SERVICE.

CORRESPONDENCE relating to the condition of the Indian Medical Service and of the medical profession in India and a despatch from the Secretary of State have recently been issued as a White Paper.[1] The first and longest document is a letter from the Government of India, Home Department, to the Secretary of State, dated Nov. 17th, 1910. This consists, first, of a brief résumé of the position of affairs since Lord George Hamilton's despatch of May, 1899, to the Indian Government, in which he asked whether means could not be found either to reduce the establishment of the Indian Medical Service or to restrict its increase; secondly, a discussion of the measures that might be adopted by Government to assist the development of an independent medical profession; and thirdly, a strong recommendation that the decision in Lord Morley's despatch of December, 1908, against any further increase in the Indian Medical Service should be reconsidered. The second document is Lord Crewe's despatch of Nov. 22nd, 1912, in reply to the preceding, in which he, speaking generally, accepts the conclusions arrived at, and adopts the view that the question of taking measures to promote the growth of an unofficial medical profession must be considered as distinct from that of limiting the cadre of the Indian Medical Service. The third is a letter from the Home Department (Government of India) to the Secretary of State, dated March 5th, 1914, indicating the developments that have taken place during the last three years and the need for an increase in the cadre of the Indian Medical Service.

Proposals in regard to Indian Medical Service.

The view of Lord George Hamilton, expressed in his despatches of 1899 and subsequent years, was that provision for the increasing medical needs of India should be met rather by encouraging the development of an independent medical profession than by increasing the establishment of the existing Indian Medical Service. He considered that it would be beneficial if European medical men were to establish themselves in private practice throughout the country in the same way as in other parts of the Empire, rather than that increased needs should be met by adding to what was primarily a military service. Lord Curzon's government in 1901 concurred in the opinion that the growing needs of India in regard to medical relief should be provided for outside the Indian Medical Service, and welcomed the growth of an independent medical profession, which, however, would be slow and gradual in its development. In 1908 the Indian Government had pointed out that about a third of the civil appointments held by the Indian Medical Service do not form any part of the war reserve, and that therefore from a military point of view there could be no objection to the transfer of these appointments to medical men not belonging to that service; such a transfer would naturally be a gradual process. It is now acknowledged that that opinion had been arrived at without consulting the local governments, and that the objections to the course proposed had been gravely underestimated. With commendable frankness the mistake is acknowledged; it is admitted that the transfer of a certain number of Government appointments from the Indian Medical Service to private practitioners would do practically nothing to encourage the growth of an independent profession; that most of the existing civil appointments held by the Indian Medical Service could not be suitably given to men not in regular Government service; and that the retention of a considerable number of superior civil appointments for the service is necessary, both for making it attractive to good men and in the interests of administrative efficiency.

---

[1] Correspondence regarding the Indian Medical Service and the Medical Profession in India. Cd. 7547. Price 2½*d*. Wyman and Sons 1914.

After referring to the different classes of medical practitioners in India, and mentioning proposals for the development of an independent medical profession, it is shown that the orders in Lord Morley's despatch of December, 1908, that there should be no increase in the civil cadre of the Indian Medical Service, and that its strength should be reduced, cause considerable administrative difficulties, and it is strongly urged that they be withdrawn. If this is not done, "the attractiveness of the service will be greatly diminished, the efficiency of the medical and sanitary administration of the country will be gravely impaired, the substitution of inferior for superior men will retard instead of accelerating the spread of Western medicine in India, and a grave amount of discontent, which could not fail to affect recruitment, will be provoked among all the Indian services which are recruited in England." This letter is signed by Lord Minto, Sir O'Moore Creagh (Commander-in-Chief), Sir G. Fleetwood Wilson (Finance Member), and the other members of the Viceroy's Council.

Reply of Secretary of State.

Lord Crewe's reply is short and in general agreement with Lord Minto's proposals. He suggested that as far as possible civil surgeoncies not reserved for the Indian Medical Service should be given to civil assistant surgeons, considering that military assistant surgeons are, as a rule, unsuitable for the work. No reasons for this being the case, and no instances that the unsuitableness actually exists, are adduced, except the fact that they are not recruited with reference to any qualifications for the duties of a civil surgeon. Lastly, the orders against increase in the civil cadre of the Indian Medical Service are withdrawn, the Secretary of State being persuaded that the considerations on which they were grounded cannot now be held sufficient to justify this step. For the two reasons of necessity for economy and desirability of increasing the number of important posts held by Indians, it is, however, still considered that the Indian Medical Service should be restricted to the military needs of the country. Moreover, the conclusions on the whole question are to be regarded as provisional in view of the inquiries to be conducted by the new Public Services Commission.

Letter from Government of India.

The letter from the Government of India, dated March 5th, 1914, refers to the proposed legislation prohibiting the issue of unauthorised medical degrees or diplomas, and introducing registration of medical practitioners, which reforms will commend themselves to all interested in medical education and practice in India. Government are strongly averse from any reduction in the civil surgeoncies held by military assistant surgeons or any diminution in the number of appointments held by these officers, considering that "the military assistant surgeon frequently makes a better civil surgeon than the civil assistant surgeon." In a concluding paragraph it is indicated that proposals may shortly be submitted by the Indian Government for an increase in the civil cadre of the Indian Medical Service in view of the growing medical needs of the country, for which the Viceroy's Council hope to show "that, looking to the work to be done, the services of Indian Medical officers [i.e., officers of the Indian Medical Service] are indispensable."

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

DURING the week the objects of this fund have been brought to the notice of many leading members of the medical profession, a fair number of subscriptions have been received, and the General Committee has been joined by, among others, Dr. A. H. F. Barbour (President of the Royal College of Physicians of Edinburgh), Professor Conway Dwyer (President of the Royal College of Surgeons in Ireland), Professor John Barlow (President of the Royal Faculty of Physicians and Surgeons, Glasgow), Sir Anderson Critchett, Dr. James Pearse, Sir William Osler, Mr. H. P. Symonds, Dr. W. Collier, Sir Isambard Owen, and Sir W. Arbuthnot Lane.

At the meeting of the Provisional Committee on Nov. 24th Dr. J. A. Macdonald, the chairman of the Council of the British Medical Association, said that in order to bring the appeal before the members of the profession generally it would be sent to the divisions and branches of the Association in the United Kingdom. In a circular letter issued by the medical secretary on Nov. 28th to the honorary secretaries of divisions and branches in the United Kingdom, it was stated that the officers of the Association fully realised that the claims on the profession at the present time are very great, but that they believed that this special appeal to doctors and pharmacists on behalf of the Belgian doctors and pharmacists was one to which nearly every member of the two professions would be glad to respond according to his means. It is understood that the Pharmaceutical Society of Great Britain is making a similar appeal through its local branches. It is known that already several divisions of the British Medical Association have arranged to call meetings and to appoint committees to raise subscriptions, and at a meeting of a Northamptonshire division on Dec. 1st it was decided to send a circular to all members of the profession in the area.

At the last meeting of the Liverpool Medical Institution the President, Dr. E. W. Hope, medical officer of health of the city, brought the Fund to the notice of the members, and the institution of a local contribution was warmly approved. Similar movements in other great centres would, of course, be very valuable.

Mr. W. J. Uglow Woolcock, the secretary and registrar of the Pharmaceutical Society, has consented to become honorary secretary to the committee conjointly with Dr. Squire Sprigge, and the hearty coöperation in the objects of the committee, expressed by the Pharmaceutical Society at a recent meeting of the council, will thus receive direct expression.

The following subscriptions to the fund have been received by Dr. H. A. Des Vœux, the treasurer, up to Tuesday evening last, in addition to subscriptions amounting to £1024 9s. 6*d.*, which were acknowledged last week. The list does not include any additional subscriptions received by the Irish committee:—

Subscriptions should be sent to Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, and crossed "Lloyd's Bank, Ltd." Subscriptions by members of the profession in Ireland may be sent to Dr. T. Percy Kirkpatrick, Registrar, Royal College of Physicians, or Dr. C. M. Benson, secretary to the Council of the Royal College of Surgeons of Ireland, at the Royal College of Physicians of Ireland, Kildare-street, Dublin.

In the first list of subscriptions Mr. J. P. Ellerington's name appears as a donor of £20. He has signified his intention of further subscribing £5 monthly for six months, and his first monthly donation is acknowledged to-day. In the same list Dr. G. Grey Turner's name is wrongly given as A. A. Turner.

The Appeal for Surgical Instruments.

The Master of the Society of Apothecaries acknowledges the receipt of surgical instruments kindly contributed by the following gentlemen since the publication of the last list:—

Dr. R. Arderne Wilson, Sausmarez-place, Guernsey; Dr. W. Horton Date, Ashley-road, Barnstaple; Dr. Pollock, Tiverton, Devon; Dr. W. Habgood, Health Department, Sutton, Surrey; Dr. Leishman, Slough; Mr. James Watson, Norwich; Dr. W. H. P. Sheehy, Montebello, Totteridge, Herts; Dr. J. B. Berry, Keighley; Dr. P. C. Maitland; Dr. J. E. Thomas, Bangor; Dr. G. A. Pirie, Airliebank, Dundee; Dr. H. A. Des Vœux, Buckingham Gate, S.W.; Dr. W. J. Harnett, Belvedere House, Barnet; Dr. Leon, Torquay; Dr. C. J. W. Dixon, Bridge-street, Hawick, N.B.; Dr. E. Smallwood, The Bays, Knight's Hill, West Norwood, S.E.; Dr. A. J. Ballantyne, Sandyford-place, Glasgow; C. W. J.

Health of the Post Office Staff.—In the report of the Postmaster-General for the year ended March 31st, 1914, it is stated that the health of the staff has again been satisfactory. The average sick-rate of the established staff was 7·9 days for men and 12·2 days for women, and of the unestablished staff 5·2 days for men and 6·0 days for women. The deaths recorded showed an annual death-rate of 3·1 per 1000 for men and 1·0 for women on the established staff. The proportion of deaths from tuberculous diseases to deaths from all causes in the Post Office was 16 per cent.; and the proportion of deaths and retirements from tuberculous diseases to deaths from all causes and retirements from ill-health was 16·1 per cent. "It appears," the report continues, "from the Registrar-General's annual return for 1911 that in the case of persons in the United Kingdom between the ages 15 and 65 the proportion of deaths from tubercular diseases to deaths from all causes was 21·0 per cent., and it therefore appears that the conditions of service in the Post Office are not, as is sometimes alleged, specially favourable to the development of tuberculosis. This is confirmed by the fact that in 87 per cent. of the cases of tuberculosis occurring during 1913 there was a history either of previous tubercular disease in the family or of previous illness predisposing to tuberculosis in the patient. Every facility is granted to Post Office servants suffering from tuberculosis to obtain sanatorium treatment where a reasonable prospect of recovery exists. It may be of interest to point out that of the cases occurring during 1913, which were completed before the end of the year, about 61 per cent. of those who received sanatorium treatment were able to resume duty as compared with 22 per cent. in the case of those who did not receive such treatment. An examination of the cases of neurasthenia occurring during 1913 showed that in the majority of cases the disease was attributable to physical causes or to domestic troubles, and that there is no foundation for the allegation that Post Office work has a prejudicial effect upon the nervous system of the staff generally."

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending Sept. 30th, 1914.

1	2	3	4	5	6	7	8	9	10	11	12
Place.	Correspondent.	Rainfall in milli-metres.	Metric tons of deposit per square kilometre during month.

Col. 4 includes all matter insoluble in water but soluble in CS_2. Col. 5 includes all combustible matter insoluble in water and in CS_2 Col. 6 includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: *(a)* Approx. 9 lb. per acre; *(b)* 2·56 English tons per sq. mile; *(c)* one gramme per sq. metre; *(d)* 1/1000 millimetre of rainfall (see Col. 3).

The analytical work involved in the above return was undertaken respectively by J. F. Liverseege, F.I.C., Birmingham; Harry Hurst, B.Sc., F.I.C., Bolton; F. Southerden, B.Sc, F.I.C., Exeter; A. R. Tankard, F.I.C., Kingston-upon-Hull; W. H. Roberts, M.Sc., F.I.C., Liverpool; S. A. Vasey, F.I.C., Director, THE LANCET Laboratory (London Meteorological Office collections); J. H. Coste, F.I.C. (Embankment Gardens, Finsbury Park, Ravenscourt Park, Southwark Park, Wandsworth Common, Victoria Park collections), London; F. L. Teed, D.Sc., Golden-lane, London, E.C.; C. C. Duncan, F.I.C., Malvern; E. Knecht, Ph.D., M.Sc., Cheadle Davyhulme, Fallowfield, School of Technology, University, Whitefield (Manchester collections); J. J. Dunn, D.Sc., Newcastle-on-Tyne; Professor W. P. Wynne, Attercliffe Burial Ground, Hillsborough Park, Meersbrook Park, Weston Park (Sheffield collections); S. H. Davies, M.Sc., York; J. W. Biggart, F.I.C., Greenock; A. Scott Dodd, B.S., F.I.C., Leith and Paisley. The correspondents referred to in col. 2 are for the most part public health authorities.

Corrections.—In the June report from Leith the results were returned in error in grains instead of grammes, and the following corrections should be applied: Col. 4, for 0·70 read 0·05; Col. 5, for 19·20 read 1·24; Col. 6, for 35·87 read 2·32; Col. 7, for 21·82 read 1·41; Col. 8, for 7·27 read 0·47; Col. 9, for 84 92 read 5·50; Col. 10, for 8·26 read 0·54; Col. 11, for 5·08 read 0·33; Col. 12, for 1·39 read 0·09.

In the June and July returns the figures for ammonia recorded for the Meteorological Office collections are based upon total nitrogen found. In subsequent returns they refer to free ammonia only.

In the May returns the figure given for ammonia at Greenock should read 0·08 not 0·82 as printed.

UNIVERSITY OF LONDON.—At the last meeting of the Senate, with the acting Vice-Chancellor Sir Alfred Pearce Gould in the chair, it was resolved to express to the Vice-Chancellor profound sympathy on the death of his son, Captain G. W. Herringham, killed in action. Among various resolutions which were passed in respect of the war was one to the effect that during the continuance of the war only the Second Examination for medical degrees, Part I., should be held in December as well as in March and July. The resignation by Dr. David Waterston of the professorship of anatomy in King's College was reported. Dr. George C. Low was recognised as a teacher of tropical medicine at the London School of Tropical Medicine, and Mr. R. Foster Moore as a teacher of ophthalmology at the Royal London Ophthalmic Hospital. The Vice-Chancellor (and, during his absence at the seat of war, the acting Vice-Chancellor) was elected chairman of the site and accommodation committee. Dr. M. S. Pembrey was appointed an internal examiner in physiology for medical degrees. Dr. Sidney Phillips and Professor Albert Carless were appointed to act as examiners in the December examinations for the M.D. and M.S. degrees, in the absence of Dr. H. D. Rolleston and Mr. F. F. Burghard respectively, who are absent on military duty. Dr. S. L. Box was nominated for reappointment as a member of the Ealing Education Committee.—At a meeting of the University of London Lodge of Freemasons held on Nov. 12th Dr. Sydney Russell Wells was installed as the thirty-first Master of the lodge.—The first annual general meeting of the members of the University of London Club will be held at the Club House, 21, Gower-street, W.C., on Wednesday next, Dec. 16th, at 8.30 P.M.

THE WAR REFUGEES' CAMP AT EARL'S COURT.

IN THE LANCET of Sept. 26th and Oct. 3rd our Special Sanitary Commissioner described the early arrangements which were made by the Metropolitan Asylums Board on behalf of the Local Government Board for dealing with the large number of Belgian war refugees reaching England at that time from Antwerp. His experiences at Tilbury and the Alexandra Palace showed clearly that the very difficult problem of receiving and disposing of our poorer guests of war had even then been taken in hand with great thoroughness. It will be remembered that the duty of providing reception hostels for the temporary housing of refugees, as well as the registration of refugees, was entrusted by the Local Government Board early in September to the Metropolitan Asylums Board, who readily placed at the disposal of the Government their machinery for dealing with large numbers of persons in an orderly fashion. In the 12 weeks which have since elapsed over 40,000 refugees have been temporarily cared for in this manner. Our Commissioner described the first beginnings of the scheme and carried the story up to what may be called, in military language, the occupation of the Alexandra Palace.

From this point until after the fall of Ostend on Oct. 15th a continuous torrent of war refugees passed through the Palace. The average daily number of admissions was about 500, while on Oct. 12th some 1200 persons were received between 1.30 and 3.30 A.M., and again when the refugee ship *Admiral Ganteaume* was torpedoed in the Channel on Oct. 26th more than 1900 persons were brought to London and admitted at the Alexandra Palace after midnight. The growing influx of destitute persons from Belgium soon made it apparent that further accommodation would be needed. Two more refugee hostels at Streatham and Edmonton were opened, and on Oct. 13th negotiations were concluded for the use of the Earl's Court Exhibition premises. The "Sunny Spain" Exhibition was closed, the buildings were cleared, and staff and equipment were collected with all speed, with the result that on the evening of the day when possession was given 1400 refugees were received between 9 and 11 P.M., and were fed and housed. The adaptation of the buildings for winter use under the name of the War Refugees' Camp has since proceeded, and there is now accommodation for 3000 persons. Using this camp as a clearing-house, it has been found possible to deal with parties arriving at all hours of the day and night to the number of 2000 persons a week. Few refugees stay at Earl's Court more than six or seven days before being drafted in small groups into various parts of the country through the organisation provided by the War Refugees Committee. In all, more than 11,000 beds were provided by the Metropolitan Asylums Board within a few weeks, and there is still room for some expansion in an emergency; but up to the present the largest number of persons dealt with in one day has been 9170. The forthcoming arrival of 25,000 more Belgian refugees from Holland will, however, increase the demand for beds.

On Sunday last a representative of THE LANCET was given an opportunity of inspecting the new Earl's Court, which has most ingeniously been transformed into an immense caravanserai. The large exhibition buildings have been broken up by screening into small dormitories. In the vast amphitheatre of the Empress Hall 1000 beds are ranged on the lofty galleries, rising from the floor, tier upon tier, to a height of 50 feet, and presenting a remarkable sight, while the subdivision of the western arcade into rooms and cubicles offers cosier accommodation for the women and children. Each refugee is provided with a bedstead, mattress, pillow, two sheets, and four blankets, and nearly 7000 of these outfits have been purchased in addition to utilising large stocks already in the Board's possession. The floor space of the Empress Theatre provides dining accommodation at clean white covered tables for over 3000 at one sitting. With the advent of winter the heating of the buildings has been undertaken, the Empress Theatre by a hot-air system and the rest of the buildings by gas radiators.

The arrangements at the War Refugees Camp, where for the present all refugees are being received, may be taken as typical. The camp is reached by special motor-buses detailed for the transport of the refugees from the London termini at which they arrive, or by special train to the West London Extension Station when particularly large numbers come. On entering the camp the baggage, including bundles of all kinds and sizes, is stored in the Princes Hall, the visitors are given a liberal supply of hot coffee and bread and butter, or a meat meal when required, and are put to bed. Next morning the refugees present themselves at the registration office, where name, age, sex, residence in Belgium, and occupation are recorded, and these particulars are subsequently forwarded to the Registrar-General at Somerset House for inclusion in a great central register of refugees. For this work, as well as for general service as interpreters, a staff of trilingual Belgians has been retained.

A large clothing depôt, well stocked by generous gifts, is served by voluntary workers, and from these the guests are supplied with enough to reach their several destinations in comfort. The local public baths, again, have been available for the refugees, and hundreds have proceeded there daily, but with the advent of colder weather a large bathroom is being fitted up in the exhibition. The sanitary accommodation generally is quite adequate for the needs of the camp; indeed, to the Flemish peasant the water-closets must seem more than palatial. The whole place is kept scrupulously clean and tidy. A large crèche equipped with cots and cradles affords opportunities for mothers to leave their babies in the care of trained nurses, while the Welcome Club has been adapted for use as a hospital.

The permanent staff of the Metropolitan Asylums Board has been largely drawn on for the administration of these great hostels. At the War Refugees Camp, in addition to Mr. G. A. Powell, the officer in charge, there are three resident medical men, a matron, and a staff of trained nurses. The extent of this work and the labours of those associated in the administration and working of these refuges are little known, and have received but passing attention in the stress and anxieties of the military campaign, but they will prove to be not the least important part played by this country in the European crisis, and will result in the building up of lasting ties of friendship with the allied nations and especially with our gallant Belgian friends. A gratifying feature of the work is the constant receipt by the officer in charge of touching letters of thanks for the welcome they have received in the camp and for the generous hospitality of the English nation from refugees of every social class, while equally pleasing to the officials engaged in the work have been the visits and appreciation of distinguished Belgians, including their Queen.

THE SERVICES.

ROYAL NAVAL VOLUNTEER RESERVE.

THE following appointments have been notified:—Surgeon: A. G. L. Reade to the *Pembroke*, for R.N. Barracks. Surgeon Probationers: T. R. F. Kerby, J. M. Harrison, S. E. G. Elliott, T. J. Lane, and G. S. Barnett, all to the *St. George*, additional, for the *Albatross*, *Earnest*, *Panther*, *Quail*, and *Seal* respectively; and G. E. Mullins to the *Leander*, additional, for the *Orwell*.

ARMY MEDICAL SERVICE.

Sir Berkeley George Andrew Moynihan to be temporary Colonel (dated Nov. 28th).

ROYAL ARMY MEDICAL CORPS.

John Hall Edwards to be temporary Major (dated Dec. 1st). Guy Neville Stephen is granted temporarily the honorary rank of Major (dated Dec. 8th). William Rees Thomas is granted temporarily the honorary rank of Captain (dated Dec. 9th). Hugh Leonard Burton is granted temporarily the honorary rank of Lieutenant (dated Dec. 9th).

The undermentioned to be temporary Lieutenants:—Dated Nov. 21st: Charles Henry Fennell, George Jackson Wilson, Albert Ernest Salkeld, and Horace Simeon Berry. Dated Nov. 23rd: George Louis Atkinson, Lionel Cecil Ferguson, Alexander George Higgins, Arthur Gilbert Michelsen Middleton, and Charles Joseph Singer. Dated Nov. 24th: Donald Clark, Henry William Teague, James Matheson, Edward Harold Hertslet Granger, and Fred Alfred Risdon Hacker.

SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Royal Army Medical Corps.

To be Lieutenants on probation:—Leo Basil Clyde Marksman, Thomas Sheedy, Alexander Guthrie Semple Wallace, William Muir Dickson, James Learmont McBean, Frank Montague Barnes, Douglas Noel Macleod, Thomas Gordon Fleming, James Swan, and Richard Patrick Starkie.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Alan Cecil Perry, Harry Evans, Basil William Brown, Arthur Patrick Kennedy, Claud Aldous Slaughter, Stanley Wall Hoyland, Joseph Harold Baird, Thomas Ottiwell Graham, Owen Hairsine, Raymond John Clansen, George Albert Cole, Richard O'Kelly, Clive Alan Whittingham, Albert Frederick Leopold Shields, Frederick McKibbin, Thomas Macnaughton Davie, Campbell McNeill Cormack, John Gray Ronaldson, Hubert Charles George Pedler, Robert Lister Horton, John Alston, Charles Robertson McIntosh, John Cameron, James Couper Brash, Francis George Macnaughton, William McMeekin Chesney, William Walker, David Murdoch Marr, John McCallum Orme, John Alexander O'Driscoll, Ivan Millar Pirrie, Edgar Stanley Rowbotham, John Forbes William Sandison, Idris David Evans, Patrick Walsh, Thomas William Clarke, John Cullenan, Francis Dighton Annesley, Ian Dishart Suttie, Henry Cuthbert Bazett, George Perkins, Cyril James Anthony Griffin, Frank Cook, Francis Henry Guppy, Robert Ellis, Francis Gerald Augustus Smyth, Clifford William Sparks, Harry Edmund Creswell, Richard Amyas Preston, Arthur Bennet Preston, Albert George William Compton, Charles Hamblin Thomas, William Campbell Mackie, Charles Dudley Maybury Buckley, Frank Percy Freeman, Henry Searle Baker, Frank Crosbie, Francis Arthur Belam, Austin Smith, Ernest Andrews Dyson, Hamilton Barrett Goulding, William Ernest Tyndall, Walter Vincent Tothill, Harry Nield, Cyril Armstrong, Norman Lockhart Joynt, Hugh Spear Pemberton, Peter Francis Ward, William John Adie, William Somerset Birch, Alexander James Ewing, Harold Emerson Rose, Richard Naunton Ouseley Moynam, Morgan Joseph Bernard Francis Burke-Kennedy, John Victor Livingstone Grant, George Guthrie Marshall, Leonard Foster Browne, Cuthbert Hastings Attenborough, Harold James Stons Morton, Reginald Heber Leigh, George Martin Chapman, James Bethune Scott, John Prosser Davies, David William John, Joseph Bannister Williamson, John Clark Pyper, Geoffrey Ward Wood, Timothy Francis Hegarty, Bernard Murphy, William Henry Wood, Henry Alphonsus Harbison, Cyril Popham, Robert Hay, Claude Joscelyn Delabere May, Charles Frederick Hacker, James Kenworthy Johnston Haworth, Laurence Heber Warneford Iredale, Cedric Overton Shackleton, Thomas Copeland Storey, George Henry Chavasse Mold, John Newton McIntosh, John Howard Owen, Alexander Boyd Foot, James Lanigan, Jeremiah John Magner, Gerald Conroy Dixon, Charles Frank Burton, Lionel Arthur Lewis, John Prince Stallard, Patrick Joseph Corcoran, and Walter Armstrong Elliott.

The undermentioned to be Lieutenants on probation:—James Bryan Fotheringham, Cecil Spurling Staddon, Robert Ievers Sullivan, Johan Frederick van der Westhuyzen, Andrew Russell Ross, Claude Henry Fischel, Frederick Martin Lipscomb, Harry Prust Rudolf, Robert William Skinner Murray, William Herron Elliott, Gifford Traill van der Vyver, and Allan Beresford Hawkins.

TERRITORIAL FORCE.

Sussex Yeomanry: Surgeon-Lieutenant John R. Steinhaeuser is seconded.

Army Medical Services.

Lieutenant-Colonel Walter C. Beevor, C.M.G., Deputy Assistant Director of Medical Services, to be Assistant Director of Medical Services to a Territorial Division, with the temporary rank of Colonel.

Colonel Damer Harrisson, Retired List, Territorial Force, to be an Assistant Director of Medical Services to a Territorial Division, with the rank of Colonel.

Royal Army Medical Corps.

North Midland Mounted Brigade Field Ambulance: The undermentioned to be Lieutenants: Fred Hollway Davies and Samuel Acheson (late Cadet Lance-Corporal, Belfast University Contingent, Senior Division, Officers Training Corps).

2nd Highland Field Ambulance: Captain David Rorie to be Major. Captain Charles Cameron to be Major (temporary). Robert Tennant Bruce to be Lieutenant.

3rd Highland Field Ambulance: George McConnell to be Lieutenant.

1st North Midland Field Ambulance: Alexander Fordyce to be Lieutenant.

2nd North Midland Field Ambulance: The undermentioned to be Lieutenants: Henry Price Malcolm and Robert John McConnell.

1st West Riding Field Ambulance: Captain Walter Lister to be Major (temporary). John H. Blackburn and John Pinder to be Lieutenants.

3rd West Riding Field Ambulance: William Wilfred James Lawson to be Lieutenant.

1st Eastern General Hospital: Michael George Foster (late Surgeon-Captain, 2nd Volunteer Battalion, Royal Fusiliers (City of London Regiment)), to be Captain. Lieutenant John Herbert Owens, from Attached to other than Medical Units, to be Lieutenant.

1st Scottish General Hospital: Officers whose services will be available on mobilisation: Harold Edgar Smith to be Captain. Captain James Smart to be Major.

1st Western General Hospital: Robert William MacKenna to be Captain.

1st South Midland Mounted Brigade Field Ambulance: To be Lieutenants: James Howard Wilkinson and George Christie Soutter.

South-Eastern Mounted Brigade Field Ambulance: Captain James Hamilton, from Attached to Units other than Medical Units, to be Major.

1st South-Western Mounted Brigade Field Ambulance: Philip Woodgate Mason to be Lieutenant.

4th London Field Ambulance: Lieutenant Alfred M. Hughes, from the 6th London Field Ambulance, to be Lieutenant.

3rd Northern General Hospital: Major George H. Pooley, from the Permanent Personnel, to be Major, whose services are available on mobilisation. Captain Arthur G. Yates, from the list of officers whose services are available on mobilisation, to be Registrar, vice Major Pooley, who resigns that appointment.

3rd East Lancashire Field Ambulance: Major William R. Matthews to be Lieutenant-Colonel (temporary).

1st West Lancashire Field Ambulance: Lieutenant-Colonel David Smart, from Sanitary Service, to be Lieutenant-Colonel (temporary).

2nd West Lancashire Field Ambulance: Brigade-Surgeon-Lieutenant-Colonel William J. Fleetwood, Retired List, Territorial Force, to be Lieutenant-Colonel (temporary).

3rd West Lancashire Field Ambulance: Major and Honorary Lieutenant-Colonel Ernest W. Barnes, from Attached to Units other than Medical Units, to be Lieutenant-Colonel (temporary). Lieutenant Mitchell I. Dick to be Captain.

1st Welsh Field Ambulance: Vaughan Bateson to be Lieutenant.

2nd Western General Hospital: The undermentioned to be Captains: Herbert Lund, Robert Ollerenshaw (late Surgeon-Captain, 4th Volunteer Battalion, The Cheshire Regiment).

1st London (City of London) Sanitary Company: Major Lewis T. F. Bryett is seconded.

1st London (City of London) Field Ambulance: James Patrick Nunan Casey to be Lieutenant.

1st East Anglian Field Ambulance: Captain Francis Ward to be Major (temporary).

3rd Home Counties Field Ambulance: Charles Edward Milnes Hey to be Lieutenant.

1st Lowland Field Ambulance: Captain William Bryce to be Major.

Northumbrian Clearing Hospital: To be Lieutenants: Arthur Sutcliffe and Robert Rutherford Lishman.

6th London Field Ambulance: The undermentioned Captains to be Majors (temporary): Henry King Dawson and John Wilfred Bird.

2nd London Clearing Hospital: Captain Frederick W. Higgs to be Major.

5th (Cinque Ports) Battalion, The Royal Sussex Regiment: Surgeon-Lieutenant Peter M. Waugh to be Surgeon-Captain.

Supernumerary for Service with Officers Training Corps.—John P. Kinloch to be Lieutenant, and John E. MacIlwaine to be Lieutenant for service with the medical unit, Belfast University Contingent, Senior Division Training Corps.

Attached to Units other than Medical Units.—Russell Eliott Wood (late Surgeon Lieutenant-Colonel, Lanarkshire Yeomanry) to be Lieutenant-Colonel. To be Majors: Captain Horace C. Colman, Captain James C. Taylor, Captain Thomas W. Banks, and Captain William J. Mackinnon. To be Captains: Lieutenant James A. Simpson, Surgeon-Captain George P. Chappel (from the 7th Battalion, The Duke of Cambridge's Own (Middlesex Regiment)), Lieutenant Robert H. Shaw, Captain Alexander Graham (from the 3rd East Anglian Field Ambulance, Royal Army Medical Corps), Lieutenant George B. Brand, Lieutenant Percy R. Bolus, Lieutenant Robert Paterson, and Lieutenant J. O. Summerhayes. To be Lieutenants: George Herbert Dominy, William Henry Hender Bennett (late Surgeon-Lieutenant, 1st Volunteer Battalion The King's Own (Yorkshire Light Infantry)), William Robertson, John Kendall Syms, Arthur Samuel Walker, George Edward Gray Mackay, Daniel Durward Brown, Huntly Nevins Pelly, William Layard Griffiths, David Edward Evans, and Thomas Pearson Caverhill.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

The undermentioned Lieutenant-Colonels, from the 2nd

Northern General Hospital, Royal Army Medical Corps, to be Lieutenant-Colonels: Thomas Churton and Thomas P. Teale.

Surgeon-Captain Reginald C. Gayer, from the Surrey (Queen Mary's Regiment) Yeomanry, to be Captain.

We are asked to state that the marks sent to us for publication against Surgeon F. C. Hunot's name in the list of successful candidates for the Acting Surgeons' Examination (*vide* THE LANCET, Nov. 28th, p. 1267) are those obtained at the Entrance Examination for the Naval Medical Service, when he obtained first place, he having been prevented by illness from attending the Greenwich course and from competing at the subsequent examinations.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7703 births and 5329 deaths were registered during the week ended Saturday, Dec. 5th. The annual rate of mortality in these towns, which had been 13·0, 14·3, and 16·6 per 1000 in the three preceding weeks, declined in the week under notice to 15·3 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 14·1, against 14·4 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 4·9 in Acton, 7·5 in Gillingham, 8·4 in Eastbourne, 8·5 in Enfield, and 8·6 in Ilford and in Bournemouth to 20·0 in Bath and in Newcastle-on-Tyne, 20·3 in West Bromwich, 21·1 in Stockton-on-Tees, 21·6 in Plymouth, and 24·7 in Gloucester and in Rotherham.

The 5329 deaths from all causes were 431 fewer than the number in the previous week, and included 439 which were referred to the principal epidemic diseases, against 440 and 448 in the two preceding weeks. Of these 439 deaths, 155 resulted from measles, 99 from diphtheria, 94 from infantile diarrhœal diseases, 48 from whooping-cough, 30 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000, and coincided with that recorded in each of the three preceding weeks. The deaths attributed to measles, which had been 167, 148, and 174 in the three preceding weeks, fell to 155 last week, and caused the highest annual death-rates of 1·4 in Smethwick, in Bolton, and in Huddersfield, 1·7 in Wigan and in Gateshead, 2·0 in Wakefield, 2·2 in Edmonton, 2·3 in Northampton, 2·4 in Rotherham, 2·7 in Grimsby, and 4·2 in Newcastle-on-Tyne. The deaths referred to diphtheria, which had been 58, 74, and 77 in the three preceding weeks, further rose to 99 last week; this was the highest number of deaths recorded from this cause in any week of the current year, and included 30 in London, 10 in Birmingham, 6 in Liverpool, 4 in Hull, and 3 each in Willesden, West Ham, Great Yarmouth, and Sheffield. The fatal cases of diarrhœa and enteritis (among infants under two years), which had been 131, 138, and 102 in the three preceding weeks, further fell to 94 last week, of which 30 occurred in London, 8 in Liverpool, and 4 each in Manchester and Newcastle-on-Tyne. The deaths attributed to whooping-cough, which had been 39, 35, and 42 in the three preceding weeks, further rose to 48 last week, and included 9 in London, 5 in Rhondda, and 3 in Bristol. The deaths referred to scarlet fever, which had been 42, 28, and 42 in the three preceding weeks, fell to 30 last week, of which 10 were registered in London, 4 in Manchester, and 2 each in Birmingham, Liverpool, Oldham, Gateshead, and Newcastle-on-Tyne. The fatal cases of enteric fever, which had been 17, 17, and 11 in the three preceding weeks, were 13 last week, and included 2 each in Wigan and Newport (Mon.).

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 5005 in the 15 preceding weeks, had declined to 4980 on Saturday last; 537 new cases were admitted during the week, against 751, 627, and 623 in the three preceding weeks. These hospitals also contained on Saturday last 1671 cases of diphtheria, 61 of enteric fever, 49 of whooping-cough, and 47 of measles, but not one of small-pox. The 1325 deaths from all causes in London were 99 fewer than the number in the previous week, and corresponded to an annual death-rate of 15·3 per 1000. The deaths referred to diseases of the respiratory system, which had been 181, 203, and 324 in the three preceding weeks, fell to 312 in the week under notice, but were 51 above the number recorded in the corresponding week of last year.

Of the 5329 deaths from all causes in the 97 towns, 198 resulted from different forms of violence and 411 were the subject of coroners' inquests, while 1489 occurred in public institutions. The causes of 44, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, and in 61 other smaller towns. Of the 44 uncertified causes of death, 13 were registered in Birmingham, 9 in Liverpool, 3 each in Portsmouth, Leicester, and South Shields, and 2 in Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1043 births and 803 deaths were registered during the week ended Saturday, Dec. 5th. The annual rate of mortality in these towns, which had been 15·2, 16·6, and 18·4 per 1000 in the three preceding weeks, slightly fell to 18·3 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 16·1, against 14·1 per 1000 in the 97 large English towns. Among the several towns the death-rate ranged from 9·5 in Hamilton, 12·3 in Perth, and 12·5 in Falkirk, to 22·9 in Leith, 23·6 in Ayr, and 25·0 in Kilmarnock.

The 803 deaths from all causes were 5 fewer than the number in the previous week, and included 79 which were referred to the principal epidemic diseases, against numbers increasing from 50 to 82 in the three preceding weeks. Of these 79 deaths, 30 resulted from whooping-cough, 20 from diphtheria, 15 from scarlet fever, 10 from infantile diarrhœal diseases, 2 from measles, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to whooping-cough, which had been 7, 13, and 25 in the three preceding weeks, further rose to 30 last week, of which 25 were registered in Glasgow and 3 in Dundee. The deaths referred to diphtheria, which had been 7, 17, and 13 in the three preceding weeks, rose to 20 last week, and included 7 in Glasgow, 5 in Aberdeen, 3 in Edinburgh, and 2 in Kirkcaldy. The fatal cases of scarlet fever, which had been 8, 16, and 25 in the three preceding weeks, fell to 15 last week; 6 deaths occurred in Glasgow, 4 in Aberdeen, and 2 in Leith. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 31 to 10 in the six preceding weeks, were again 10 last week, of which 4 were recorded in Glasgow, 3 in Dundee, and 2 in Aberdeen. The 2 deaths referred to measles occurred in Glasgow, and the fatal cases of enteric fever in Glasgow and Coatbridge.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 163 in the 11 preceding weeks, were again 163 in the week under notice; 34 deaths resulted from different forms of violence, against 26 and 39 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 549 births and 464 deaths were registered during the week ended Saturday, Dec. 5th. The annual rate of mortality in these towns, which had been 17·7, 18·3, and 19·4 per 1000 in the three preceding weeks, further rose to 20·1 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 17·4, against corresponding rates of 14·1 and 16·1 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 24·5 in Dublin (against 15·3 in London and 19·1 in Glasgow), 21·2 in Belfast, 14·3 in Cork, 10·1 in Londonderry, 25·7 in Limerick, and 13·3 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 13·5 per 1000.

The 464 deaths from all causes were 15 in excess of the number in the previous week, and included 42 which were referred to the principal epidemic diseases, against 44 and 40 in the two preceding weeks. Of these 42 deaths, 12 resulted from infantile diarrhœal diseases, 8 from measles, 8 from scarlet fever, 6 from diphtheria, 4 from enteric fever, and 4 from whooping-cough, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against corresponding rates of 1·3 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 10, 13, and 10 in the three preceding weeks, rose to 12 last week, of which 5 were recorded in Belfast and 4 in Dublin. The deaths referred to measles, which had been 9, 10, and 14 in the three preceding weeks, fell to 8 last week, and were all registered in Belfast. The fatal cases of scarlet fever, which had been 14, 12, and 10 in the three preceding weeks, further declined to 8 last week, and included 3 in

* Including membranous croup. † The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

Belfast. The deaths attributed to diphtheria, which had been 3, 4, and 2 in the three preceding weeks, rose to 6 last week, of which 3 were recorded in Dublin. The 4 deaths referred to enteric fever were slightly in excess of the average in the earlier weeks of the quarter, and were all registered in Dublin. Of the 4 fatal cases of whooping-cough, which were equal to the average in recent weeks, 2 occurred in Belfast and 2 in Cork.

The deaths referred to diseases of the respiratory system, which had been 67, 85, and 100 in the three preceding weeks, fell to 90 in the week under notice. Of the 464 deaths from all causes, 150, or 32 per cent., occurred in public institutions, and 2 resulted from various forms of violence. The causes of 12, or 2·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion did not exceed 0·8 per cent.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1914.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 12·5 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 7·5, 11·6, and 14·0 per 1000 respectively. The lowest rates last month were recorded in Chelsea. Hampstead, Holborn, Bermondsey, and Wandsworth; and the highest rates in Paddington, Hammersmith, Stepney, Deptford, and Greenwich. The prevalence of scarlet fever showed some decrease from the very high point reached in the preceding month; the greatest proportional prevalence was recorded last month in Paddington, Hammersmith, Fulham, Stepney, Battersea, Deptford, Greenwich, and Lewisham. The Metropolitan Asylums Hospitals contained 4956 scarlet fever patients at the end of last month, against 3199, 4157, and 4561 at the end of the three preceding months; the weekly admissions averaged 661, against 414, 598, and 618 in the three preceding months. Diphtheria also was slightly less prevalent in November than it had been in the previous month; the greatest proportional prevalence of this disease was recorded in Hammersmith, St. Marylebone, the City of London, Bethnal Green, Stepney, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 1630 diphtheria patients at the end of last month, against 1030, 1296, and 1489 at the end of the three preceding months; the weekly admissions averaged 247, against 128, 188, and 213 in the three preceding months. Enteric fever was rather less prevalent than in any of the three preceding months; the metropolitan boroughs in which the greatest proportional prevalence of this disease was recorded last month were Chelsea, the City of Westminster, St. Marylebone, Hampstead, Stepney, Poplar, and Greenwich. There were 63 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 39, 57, and 65 at the end of the three preceding months; the weekly admissions averaged 8, against 11 in each of the two preceding months. Erysipelas was proportionally most prevalent in Stoke Newington, Hackney, Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Bermondsey. The 47 cases of puerperal fever notified during the month included 6 in Stepney, 6 in Poplar, 5 in Wandsworth, and 4 each in Fulham. Finsbury, and Southwark. The 2 cases of cerebro-spinal meningitis belonged respectively to Kensington and Wandsworth; and of the 10 cases of poliomyelitis 3 belonged to Islington, 2 to Hampstead, and 1 each to Bethnal Green, Stepney, Poplar, Wandsworth, and Camberwell.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the four weeks ending Nov. 28th the deaths of 5045 London residents were registered, equal to an annual rate of 14·6 per 1000; in the three preceding months the rates had been 12·6, 15·5, and 14·1 per 1000 respectively. The death-rates last month ranged from 10·4 in Lewisham, 11·4 in Wandsworth, 11·9 in the City of London, 12·1 in Fulham, and 12·3 in Woolwich, to 17·3 in Southwark, 17·4 in Holborn and in Bermondsey, 18·9 in Shoreditch, and 20·0 in Finsbury. The 5045 deaths from all causes included 158 from measles, 38 from scarlet fever, 80 from diphtheria, 34 from whooping-cough, 12 from enteric fever, and 147 from diarrhœa and enteritis among children under 2 years of age The lowest death-rates from these infectious diseases were recorded in Kensington, Stoke Newington, Camberwell, Greenwich, Lewisham, and Woolwich; and the highest rates in Hammersmith, Hackney, Finsbury, Shoreditch, and Bethnal Green. The 158 fatal cases of measles were 28 above the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Hammersmith, Hackney, Shoreditch, Stepney, and Southwark. The 38 deaths from scarlet fever were 18 in excess of the average number; the greatest proportional mortality from this disease was recorded in Chelsea, the City of Westminster. Hampstead, Battersea, Deptford, and Woolwich. The 80 fatal cases of diphtheria were 33 above the average; this disease was proportionally most fatal in St. Marylebone, Hampstead, Bethnal Green, Stepney, Poplar, Southwark, and Deptford. The 34 deaths from whooping-cough were 8 below the average; the highest death-rates from this disease were recorded in Hammersmith, Finsbury, Shoreditch, Bethnal Green, and Lambeth. The 12 deaths from enteric fever were equal to the average, and included 2 in Lambeth and 2 in Greenwich. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Paddington, Finsbury, Bethnal Green, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 28·3 per cent. above the average.

HOSPITAL SHIPS AND TYPHOID FEVER AT CALAIS AND DUNKIRK.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THOSE who realise the difficulties and dangers which must be incurred in the hasty removal of the sick and wounded in the vicinity of the fighting line—compare the retirement from Antwerp and Ostend as the enemy was rapidly closing in upon those towns—must naturally commend the idea of hospital ships stationed in seaports near to the fighting line. How useful they would have been is perhaps only realised when their great value has gone, but it is as well to docket experience for future employment. There are objections doubtless, especially structural objections, to hospital ships; but for the moment the question is not what constitutes an ideal hospital, but what is likely to prove most serviceable in war. Now, during the present war the Channel and North Sea ports, from Antwerp to Havre, have all been near to the western battlefields. The great bulk of both the British and the Belgian wounded are brought to Boulogne, Calais, and Dunkirk. They were not, however, kept on board floating hospital ships, but were brought over at once to England unless considered too seriously injured to endure the sea journey. The question that may fairly be mooted is whether there is not room for hospital ships in this organisation. With the approach of winter, and in spite of all the care taken, the amount of sickness will increase, and although, so far as our own troops are concerned, the general health is good, yet as the number of surgical cases has declined the number of medical cases has gone up. The inclement exposure and the necessary conditions of trenches in winter-time must favour the spread of many pathological conditions, and as the cases grow more numerous the desirability of separating the sick from the wounded becomes more pressing. Now when it is a question of receiving the wounded, whether British or foreign, and distributing them throughout the whole country, the difficulty is a more circumscribed one than that caused by the arrival on these shores of a large number of sick. Not only will there be cases among them that could ill-support the sea journey—that has occurred among the wounded—but there will be cases that have not been diagnosed and others whose reception must be guarded by public health precautions.

Hospital Ship for the Sick at Dunkirk.

The question has been already debated, although in the stress of events it has attracted no public attention. When during the month of November the Wounded Allies Relief Committee sent a deputation over to Dunkirk, they discussed this matter with the Belgian Minister of War, Baron de Broqueville. It was then generally agreed that it would be preferable not to send the sick soldiers to England but to treat them in France. Surgeon-General Mellis was very emphatic on the advantage of having a hospital ship in Dunkirk harbour. This was within 15 to 20 miles from the trenches defended by the Belgian troops. If they succeeded in fighting their way back into

Belgium the hospital ship could follow the victorious armies up to Ostend and perhaps eventually even up to Antwerp. But, on the other hand, if the Germans did succeed in breaking through and made a sudden rush on Dunkirk, as they did on Antwerp and Ostend, what a great relief it would be to know that at least the sick were safe, that they need in no wise be disturbed. On the approach of danger steam should be kept up and in a few turns of the screw the hospital ship would be making for the nearest secure haven. The advantages of such an arrangement are obvious, especially to those who have any conception of the ghastly struggle that took place to get the wounded on board the ships at Ostend before the Germans invaded the town. Consequently the deputation on their return from Dunkirk at once brought the whole question before the Admiralty. They suggested that one of the German liners which had been captured might be converted into a hospital ship. To this some objection was made because the legal ownership of these prize ships had not yet been clearly defined. Then there is, it appears, a German boat that was got up to look like a hospital ship, but is supposed to have been employed for the laying of mines. Now there would be a sort of retributive justice if this vessel was converted into a genuine hospital ship. However, on closer examination it was found that this proposal was not very practical. In the interval a former liner has been inspected, and hopes are entertained that it will be possible, without much further loss of time, to convert her into a hospital ship to be stationed in Dunkirk harbour.

Hospital Ship for Typhoid Fever Cases at Calais.

While these negotiations are proceeding another and much graver matter, the presence of typhoid fever in the northern fighting area, has to be considered. At the beginning of the month Major H. Stedman, R.A.M.C., writing to the *Times* from Calais, announced the occurrence of cases of typhoid fever in that city in numbers which seemed to be assuming the proportions of an epidemic. The existence of numerous cases is undoubted, but the extent to which the Belgian army is affected has been exaggerated, authoritative information putting the number of cases in that army at only 120. Still, the danger is present. The civil population in West Flanders and the north-east of France is likely to suffer together with the Belgian army and such French and British troops as may be near at hand unless the preventive measures now being rapidly and drastically undertaken are successful. Major Stedman described some 20 to 30 fresh cases arriving per day at Calais, and made no exaggerated demand when he suggested there should be a hospital ship in the harbour large enough to take at least 300 cases from the town of Calais. The medical correspondent of the *Times* reports that a convent at La Panne has now been secured as an isolation hospital. The joint committee of the British Red Cross Society and the Order of St. John have made a grant of £10,000 to be expended at once, under the direction of Sir Arthur Sloggett, acting as their chief commissioner, and we must all hope that the evil taken in hand quickly will soon be got under.

A Further Effort Needed.

There are ships and to spare lying idle in English docks. Many of them are prize vessels, and if they can be immediately employed for a useful purpose, this being war time, little legal points should not be allowed to stand in the way. If, as seems most probable, a big ship can be converted into a big hospital more rapidly and more cheaply than a new hospital can be built on shore, there should be no hesitation. An epidemic may be as fatal and represent as great an emergency as a decisive battle. When artillery comes into action no delay is allowed so as to ascertain the private property rights that exist within the range of fire. If we have ships that can be used let us use them with equal alacrity. Already the admirable care taken to supply ample food to our troops in the field and to watch over the sanitation of camp and trench has saved thousands of lives. Now a further effort is needed. The heroic but shattered Belgian army has no longer any hospital accommodation remaining, and probably it has not the means of sterilising the water drunk by the brave troops it still keeps in the field. Let us at once and promptly supply both.

All along the line from Nieuport to Ypres, especially in the neighbourhood of Dixmude, the floods that have barred the way to the invaders have emptied cesspits and middens and spread their contents far and wide. In these waters there are also many corpses. According to the uncertain news that reaches us from the German side, typhoid fever already seems to be far more prevalent among our enemies than among our friends. That, however, only adds to the danger on both sides by augmenting the risks of water contamination. Therefore we need at once, and on the largest possible scale, means for sterilising water, for destroying the dejecta of patients, and isolation hospitals.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Tetanus.

THE treatment of tetanus properly engages the attention of the medical world at present, for whatever may be the nature and gravity of wounds in themselves, all alike become, if not incurable, at least very difficult to deal with when they are accompanied by tetanus. At the Académie des Sciences on Nov. 9th the Prince of Monaco read a communication by Dr. Caillaud and Dr. Corniglion on a method recently practised by them in the hospital of Beausoleil on four patients showing symptoms of differing intensity, two mild and two very severe. They had recourse to Baccelli's method of injections of phenol, to which were added intravenous injections of lantol or colloidal rhodium. The phenol was used in a 1 per cent. solution, an intramuscular injection of 40 c.c. to begin with being given daily. This amount was progressively increased to 70 c.c., then decreased after a clear amelioration of the patients' condition. Later the 1 per cent. solution was replaced by a 2 per cent. solution, the doses of which were naturally halved. Of lantol, in the two very grave cases, an intravenous injection of 6 c.c. was made every two days until all danger seemed to be over, in these cases about eight days. The four cases thus treated were cured. The sole inconvenience noted was an indurated erythema following the use of the 2 per cent. solution, which, however, quickly disappeared. The improvement occurred rapidly and progressively, a definitive cure being obtained in from 15 to 20 days. The authors also state that the same treatment practised at Cannes was successful in all of five cases treated.

Medical Life in Paris.

The Académie de Médecine has had before it some very interesting subjects, all naturally having relation to warfare. M. Walther discussed surgical intervention in the injury of nerve trunks of limbs caused by projectiles. He has operated six times. When the pains are very lancinating it is desirable to operate early before cicatrisation of the cutaneous wound. In cases with complete paralysis but without pain it is better to await cicatrisation of the wound. The results of these operations have been very satisfactory. M. Langlet, the heroic mayor of Rheims, has been unanimously elected to the vacant National Associateship at the Académie de Médecine. The Academy was indeed happy thus to testify its admiration for his valiant attitude in the recent misfortunes of the city. On Nov. 24th Dr. Tuffier called attention to the use by Germans of explosive bullets obtained by reversing the bullet in the cartridge, so that the point was in contact with the powder, the flat soft core of the bullet being thus exposed. Bullets thus used are violently explosive on contact with resistance. Their range is of course very much lessened, but with trenches in close vicinity that is a matter of small importance. Cartridges thus converted have been found in rifles collected on the field and in the pouches of soldiers. M. Terson read a communication on the treatment of wounds of the eye, which have been very prevalent in this war. In it he showed the dangers of certain useful antiseptics when applied to the eye and detailed the necessary precautions. He reported several of his cases of extraction of projectiles, and recommended the suture of wounds of the eye, facilitated by new methods and material, with a view to avoiding ablation of the eye. At the Académie des Sciences M. Laveran dealt with exanthematic typhus and insisted on its prophylaxis, which is very simple. M. Laveran recalled that as typhus was rapidly developing in the German trenches it was necessary when German prisoners were taken to subject them to the necessary hygienic cleanliness, the non-observance of which would threaten the allied lines, which are at present happily free from it. It must be remembered, however, that the Germans use the word "typhus" with or without qualification for enteric fever sometimes. Finally, at the Société de Biologie M. Weinberg has reported some of his studies from the bacteriological point of view into a certain number of cases of gaseous gangrene among the English wounded.

The Diminution of the Birth-rate in France.

The diminishing birth-rate, disquieting as it always is, is more so at the present time, when it has so important a bearing on events. The births fell from 750,651 living children in 1912 to 745,539 in 1913. So low a figure had never been recorded, with the exception of 1911, when it was regarded as deplorable. To estimate the lamentable and continued shrinkage of the French birth-rate it suffices to recall that the annual mean of living births was 945,000 during the period 1872 to 1875, that since 1907 the number of births has fallen below 800,000, and since 1911 below 750,000. That is to say, that in less than 40 years the births in France have diminished by 200,000 a year. The proportion of living children notified to 10,000 inhabitants was 188 in 1913, as against 190 in 1912, 187 in 1911, 196 in 1910, and 205 in 1906. The shrinkage increases year by year. It is true that in all the great countries of Europe the birth-rate is decreasing, but in a much less degree than in France, and, moreover, the annual excess of births over deaths is proportionately from six to ten times greater than in France. Thus, for 1912 the excess of births over deaths per 10,000 inhabitants was in France only 15. In the same year it was in the Low Countries 158, in Italy 140, in Hungary 130, in the German Empire 127, in Austria 107, and in England 105. Last year the excess was 41,901 births, or only 10 per 10,000 inhabitants. The excess of 1912 was 57,911, or 15 per 10,000. There has thus been a diminution of one-third. This diminution springs from a simultaneous deficit of 5112 births and an increase of 10,898 deaths. Last year an excess in births was noted in 49 departments in place of in 56 in 1912. The departments in which the birth-rate exceeds the mortality are those of the Nord, Pas de Calais, Bretagne, the frontier regions of the Nord-Est, Limousin, and Corsica. On the other hand, Normandy and Dauphiny continue to depopulate. The proportion of births per 10,000 inhabitants was 196, as against 198 in 1912. The departments in which the birth-rate was highest were Pas de Calais, 266 children per 10,000 inhabitants; Finistère, 259; Morbihan, 248; Seine-Inférieure, 240; Meurthe and Moselle, 239; Côtes du Nord, 236; Lozère, 219; Doubs, 217; Nord, 216; Mayenne, 213; Vendée, 211; and Vosges, 210. Those in which it was lowest are the Valley of the Garonne and Bourgogne; Gers, 129; Lot et Garonne, 134; Yonne, 137; Nièvre, 141; Allier, 143; Lot, 145; Haute Garonne, 147; Gironde, 148; and Ariège, 149. The number of deaths, 703,638 (stillbirths 31,119 excluded) is greater by nearly 11,000 than that of 1912, which was the lowest recorded since the beginning of the present century. The ratio of deaths for the entire population was 178 per 10,000 inhabitants, as against 172 in 1912, 196 in 1911, and 179 in 1910. The death-rate has risen in 64 departments, and particularly in the Bouches du Rhône, the Dordogne, the Var, Haute Savoie, Corsica, the Somme, Haute Vienne, Aveyron, and Tarn-et-Garonne. The Norman and Breton departments continue among those furnishing the largest proportion of deaths.

Ambulance Barges.

Four ambulance barges, each containing 125 beds, with full necessary equipment, including radiographic installations, moored on the Seine at Paris, were officially inspected and approved on Nov. 26th. These vessels search such districts as they can reach for wounded and transport them to the base hospitals. Each vessel has a complete medical and nursing establishment. They are towed at a rate of 100 kilometres in 24 hours.

Dec. 7th.

Obituary.

WILLIAM OSCAR JENNINGS, M.D. PARIS, M.R.C.S. ENG.

THE death of Dr. Oscar Jennings, formerly of Paris, took place suddenly in Ramsgate on Nov. 23rd, aged 63. He only returned to this country to live in October of last year, after a residence in Paris of about 35 years.

William Oscar Jennings was born in London in 1851. He studied medicine at Guy's Hospital and in 1873 was admitted a Member of the Royal College of Surgeons of England. After qualifying he went to New Zealand, where he practised for two years, but in 1875 he returned to Europe and settled in Paris. He entered the University there, and after passing the necessary examinations graduated as M.D. Paris in 1878, choosing for his thesis the subject of Metallotherapy. He became closely associated with Professor Ball and thus his mind was turned in the direction of mental and nervous diseases. In 1878 he published a comparison of the effects of various forms of treatment in hysteria. In 1882 he translated into French Gowers's "Diseases of the Spinal Cord," and in the following year Weir Mitchell's book on "Neurasthenia." In the meantime he had become a strong supporter of Sayre's mechanical treatment of spinal complaints, a method which at that time found few adherents in France, and published in French a book thereon. In 1887 Dr. Jennings was appointed medical electrician to the Clinique des Maladies Mentales at the Asile Ste. Anne. About the same time he became enthusiastic on the subject of cycling from a hygienic point of view, and in 1888 he published "La Santé par le Tricycle," which reached a third edition in the following year. He accomplished much for the popularisation of cycling, both by subduing prejudice and by combating the apprehensions of the profession concerning its possible dangers, especially in regard to women, and his services in this direction were recognised by the Union Velocipédique Française, which awarded him its gold medal.

Of late years Dr. Jennings had devoted himself to the study of the morphia habit, on which he published several books, besides a number of articles in French medical periodicals and in the columns of THE LANCET. The essentials of the method of treatment recommended by him consisted in supporting the heart during the period of enfeeblement that immediately follows withdrawal of the drug, and in the neutralisation of the hyperacidity by sodium bicarbonate. He also called attention to the local erythematous patches and the puffiness of the face that accompany the toxic effect of antipyrin, which is sometimes associated with the taking of even very moderate doses. In 1912 he published in French a very interesting historical and therapeutic essay on the Russo-Turkish bath, and he was engaged upon further literary work on the same subject at the time of his death. During a large part of his residence in Paris he acted as the Special Correspondent to THE LANCET.

Dr. Jennings was buried at Hendon Park Cemetery. He was entitled to sepulture in Père La Chaise, but the circumstances of the war forbade removal of the body to Paris. He leaves a widow and one daughter.

ROYAL HANTS COUNTY HOSPITAL.—At the last quarterly meeting of the Court of Governors it was stated that since the commencement of the war 22 cases of British wounded had been received, 68 wounded Belgians, and 87 cases of accident or illness from the military camp in the neighbourhood of Winchester. Fewer applications for admission had been received from the civil population. An overdraft of £3222 3*s.* 5*d.* was reported, as compared with £2792 19*s.* 10*d.* at the beginning of the quarter.

CIVIL AND MILITARY SANITATION IN THE TROPICS.—The first of two Chadwick public lectures was delivered by Sir Ronald Ross, K.C.B., F.R.S., at the London School of Economics on Dec. 4th, Sir James Crichton-Browne (Chadwick trustee) being in the chair. The lecturer pointed out that the relations between administration and public sanitation had not been completely discussed. The older theory of government, well enunciated by David Hume, was that government had "no other object or purpose but the distribution of justice." This idea had now been abandoned in favour of the view that government should do everything possible for the prosperity of its subjects. The lecturer then traced the history of tropical sanitation. Civilisation had been excluded from large tropical areas such as tropical Africa, largely because grave tropical diseases were present which had not been investigated until recently. The causes and prevention of many of these maladies were now understood; but the question still remained whether public administration could utilise the preventive measures suggested by science. Examining the history of this question, the lecturer pointed out that in the old days medical and sanitary matters were originally in the hands of the priestly caste, many of whose religious injunctions were really of a sanitary nature. In the Middle Ages little attention was given to sanitary matters, and epidemics often provoked ridiculous attempts at prevention. The modern history of tropical sanitation began from the time when the European nations commenced colonisation. About the middle of last century sanitation in Europe began to approach its modern growth and naturally affected tropical sanitation.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of THE LANCET.

SIR,—Will you allow me to call the attention of your readers to the educational and pecuniary advantages offered by Epsom College to the sons of medical men. These are briefly described in the advertisement appearing on the outside page (iv.) of the present issue of THE LANCET; but I should like in this letter to emphasise the facts that this year 10 boys out of 13 passed the whole of the first examination for medical degrees of the University of London, and that 18 boys out of 23 passed the matriculation examination of the same University, six of them gaining a first class.

May I also take this opportunity to remind those of your readers who are not already subscribers to the Royal Medical Foundation attached to Epsom College that this Foundation provides gratuitously an education of the highest class, together with maintenance, clothing, and pocket money, for 50 necessitous sons of medical men, and gives pensions of £30 each to 50 aged members or widows of members of our profession in reduced circumstances.

It is necessary to procure a sum of about £4500 a year in voluntary contributions to enable the continuance of these benefits to the medical profession; and as the numerous calls in connexion with the war are causing both the withdrawal and the curtailment of some annual subscriptions, I trust that numerous fresh contributors will be forthcoming to assist and encourage the Council at a particularly anxious time.

I am, Sir, yours faithfully,

HENRY MORRIS,
Honorary Treasurer.

Nov. 30th, 1914.

GAS GANGRENE.

To the Editor of THE LANCET.

SIR,—The report signed by Sir Anthony Bowlby and Dr. Sidney Rowlands which you have published on gas gangrene amongst our troops, in THE LANCET of Nov. 28th, is of considerable interest. A short account is given of the bacteriological findings, clinical aspect of the disease, and what they consider to be the necessary methods to adopt for the prevention of the spread of infection to others. Sir Anthony Bowlby and Dr. Rowlands state in this report that in their opinion the infection is directly due to wound contamination from the soil. In the Transactions of the Pathological Society of London in 1905 Mr. Percy Sargent and I published two cases of gas gangrene due to the bacillus aerogenes capsulatus and caused by infection of the wounds with street mud. We refer to the beneficial action of hydrogen peroxide on this type of infective gangrene. Since that paper was published in 1905, I have seen a large number of cases of gas gangrene due to the bacillus aerogenes capsulatus, and in every case the wounds were contaminated with manured earth or street mud. In several instances continuous flooding of the tissues with hydrogen peroxide (20 vols.) through deep incisions has led to recovery by rapid reduction of the general toxæmia and of the local condition.

Sir Anthony Bowlby and Dr. Rowlands draw special attention to the bruising of the tissues in their cases and to the slight degree of pyrexia. In every case which I have seen bruising of the tissues has been most obvious and appeared to be closely related to the actual starting point of the gas gangrene, but severe pyrexia occurred in several of the cases which I have investigated. Probably the most interesting fact for discussion is the presence of the bacillus aerogenes capsulatus in the tissues without gas gangrene. I have cultivated this organism from cases of peritonitis, puerperal fever, bone abscess, and cystitis without the slightest evidence of emphysematous gangrene of the affected tissues, and although no special precautions have been taken by the nursing staff and those in charge no case of direct infection has ever occurred to my knowledge. This fact is of special importance when we consider the comparative frequency of severe infections caused by streptococci among those who come in direct contact with the infected tissues. It might be of interest to refer to a case of suppurative arthritis due to a shrapnel wound from which I obtained a pure culture of the bacillus aerogenes capsulatus. Gas gangrene was not present at the time of operation, and did not develop subsequently, although the infected pus came in direct contact with the wound. These observations on infections caused by this bacillus in man are in accordance with our knowledge of the subject derived from experimental data. Spreading gangrene can be readily produced in guinea-pigs by inoculating the animals with the bacillus, together with some fluid, which in itself is capable of acting upon the healthy tissues. An active growth of the organism in milk affords perhaps the most favourable material for experimental purposes. In my experience everything tends to show that this bacillus requires especially abnormal tissues before it will incite gas gangrene, otherwise it may simply give rise to ordinary suppuration. Whether the gas gangrene to which Sir Anthony Bowlby and Dr. Rowlands refer in their report is due to the bacillus aerogenes capsulatus alone or to other anaerobic bacilli with distinctive and practical differences will no doubt be finally settled.

I am, Sir, yours faithfully,

Dec. 6th, 1914. LEONARD S. DUDGEON.

"STRUMOUS HABIT OF BODY."

To the Editor of THE LANCET.

SIR,—Mr. Percy Dunn desires to know precisely what I mean by the term "strumous habit of body." I will try to explain to him as concisely as I can. I think we must go back to Celsus for an early use of the term struma. We find it now commonly used as a euphemism for scrofula, being a less disquieting one to employ when speaking of this condition in polite society. It is less precise than the term scrofula, because it has been, and still is, applied to other diseases—e.g., goitre—and it is employed to designate many lesions which are regarded as solely dependent on tuberculous invasion, which means no less and no more than the intrusion and growth of the bacilli of tubercle in various textures of the body.

In 1846[1] Dr. Robert M. Glover shrewdly propounded what I venture to regard as the correct view of this matter, pointing out that a careful distinction must be made between the predisposing constitution and the actual processes of tuberculosis, between the *ens in potentia* and the *ens in actu*, and that thus the subjects of scrofula widely diverged from normal health before tuberculous deposits took place. Mr. Dunn is therefore correct in presuming that I regard "scrofula" (but not necessarily) "as a pre-tuberculous state." He, however, proceeds to maintain that reasons exist for believing that the term, so considered, is misleading because many of the lesions now commonly called scrofulous are really manifestations of tuberculosis. I agree so far, but when he sets forth his main reason for objecting to the term strumous habit of body I must decline to accept his view of the question as set forth in the following paragraph: "Strumous symptoms, so-called, which are not tuberculous are evidence of perverted metabolism, due to hypothyroidism, the proof of which is furnished by the fact that under thyroid treatment these strumous symptoms vanish." Mr. Dunn thus alleges that he has abolished scrofula. This is good news for the victims of the strumous habit of body, for if we can materially alter this inborn textural quality we shall greatly reduce the inroad of tuberculous disease in multitudes of people.

A diathesis, or bodily habit, represents a soil, and this soil is favourable or unfavourable in different subjects to various irritants or infections. This doctrine, which has long been held and taught in the Edinburgh and Parisian schools, and by Paget, represents a great truth in practical medicine. Modern studies in bacteriology have largely confirmed the value of this teaching. To-day too much attention is paid to the seed, while the soil is largely ignored. The idea that "scrofula is tuberculosis," as declared by Koch, is in my view utterly wrong, and this opinion issued from the laboratory and not from clinical study. A scrofulous individual is all his life scrofulous, whether he be infected with tubercle or not. As has been well declared, "On nait, on vit, et l'on meurt scrofuleux." Tuberculous disease is only too likely to alight and flourish in such subjects, but it is no essential part of this abnormal habit of body. Scrofulous persons may, and certainly do, often reach old age, under favourable conditions, without contracting any overt or disabling tuberculous lesions. They commonly provide a favourable soil for all irritants and infections, being vulnerable beyond others, and slow to heal.

Lastly, I would note the fact in relation to this correspondence that in obvious cases of hypothyroidism such as myxœdema and cretinism, we rarely encounter tuberculosis as a complication.

I am, Sir, yours faithfully,

Grosvenor-place, S.W., Dec. 5th, 1914. DYCE DUCKWORTH.

THE RADICAL CURE OF VARICOCELE.

To the Editor of THE LANCET.

SIR,—It is possible that a very simple method of excising affected veins may be useful at this time when many youths wish to have defects removed in order to fit them for active service. Even at the risk of being considered absurdly elementary, I venture to mention a few anatomical facts well known to medical students. The pampiniform plexus consists of eight to ten veins, which lie in front of the vas deferens, with the peculiarity—suspension of tortuous vessels, with defective valves, feebly supported in loose areolar tissue, a combination which favours dilatation and sagging. And it is almost superfluous to add that the affection commonly known as varicocele is essentially a varicose condition of this anterior bundle of veins. Surgical intervention must be confined solely to excision of the offending vessels in order to avoid possible interference with the normal circulatory requirements of the testis.

---

[1] Fothergillian Prize Essay.

If a little attention be devoted to the following simple manœuvre there will be no reason to fear subsequent testicular atrophy. Standing on the left side of the patient for left varicocele, I firmly grasp the whole structures of cord, midway between the external ring and testicle, between my left thumb and left index finger. Having assured myself that I feel the vas deferens securely fixed in its normal posterior position and the included skin between fingers rendered taut, I make a 1 to 2-inch incision over bulging part. With a few horizontal strokes of the knife the infundibuliform fascia is exposed, and when this is opened the pampiniform plexus juts into the wound. With a little further dissection the presenting veins are thoroughly exposed through the whole length of the incision; these are now caught up in mass by a pressure forceps, and the handle of scalpel completes their isolation from underlying structures. Catgut ligatures are then applied above and below, and an intervening segment (2 inches) of varicose clump excised. The stumps are approximated and testicle elevated by tying the upper and lower ends of the ligature together (Bennett).

The one cardinal factor in this three-minute, three-instrument (knife, forceps, and needle) procedure is boldly to continue horizontal strokes with the knife, and not to relax the left thumb and finger grip until the pampiniform plexus pops into view.—I am, Sir, yours faithfully,

JOHN O'CONOR, M.A., M.D. T.C.D.,
Senior Medical Officer, British Hospital, Buenos Aires.
Oct. 24th, 1914.

CHLORALOSE AS AN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—Some few years ago Professor Richet, of Paris, introduced chloralose, a compound of chloral and glucose, as an anæsthetic for animals in experimental physiology. Although it is not much used in this country it is an invaluable drug for the purpose. Having had some experience of its very satisfactory action in cats and dogs it seemed to me that there is no valid objection to its use, or at any rate to giving it a trial, for general anæsthesia in man. Such trial may have been given it, but if any published reference to it has appeared it has escaped my notice.

Chloralose can be administered by the mouth, by the rectum, or subcutaneously. It is rather insoluble, but is very easily mixed with milk or butter. Mixed with the latter and spread on a bit of bread it is readily swallowed by a dog, and this is the method usually adopted by me. About 20 or 25 minutes after swallowing it the animal begins to show symptoms. The first thing noticed is a weakness of the hind limbs and a staggering gait. This weakness continues until paralysis of these limbs sets in at a time when the fore part of the body is still supported by the fore-limbs, so that the attitude is characteristic. In this stage or a little earlier salivation begins, and without evidence of restlessness or excitement the paralysis spreads to the fore-limbs. The animal is still fairly wide awake though stupid and shows no sign of discomfort or anxiety. Finally it goes quietly to sleep.

The reflexes are all unaffected or slightly exaggerated, the superficial more so than the deep. Before sleep supervenes the animal recognises a threatening movement, but the sense of sight apparently goes before that of hearing. For some time after the eyes have been closed in sleep the animal responds to sound, such as a whistle, by a pricking of the ears or a movement of the head. Even very slight sounds cause a response at a time when the animal is past opening its eyes, but ultimately a stage is reached about one hour or a little more after the dose is swallowed, when sound fails to cause a response. The reflexes are unimpaired throughout. In the early stages of paralysis onset the animal may walk about and may void urine. In such a case it sometimes topples over, but there is no sign of distress or discomfort. More often it remains quiet from the start.

The dose is 1 gramme per kilo of body weight. The anæsthesia is complete and lasts about two hours. A smaller dose may be employed and supplemented with ether.

From the humane point of view, if from no other considerations, chloralose is a very desirable anæsthetic in animals which sometimes show nervousness before being brought under the effects of such anæsthetics as ether, chloroform, &c. For effectiveness and convenience it is far superior to an anæsthetic which has to be continuously administered with careful observation and control of anæsthesia depth.

I am, Sir, yours faithfully,
D. T. BARRY, M.D. R.U.I., F.R.C.S. Eng.,
Professor of Physiology, University
College, Cork.
Nov. 22nd, 1914.

DISTRICT NURSING IN LONDON.—The inaugural meeting of the Central Council for District Nursing in London was held on Dec. 1st at the Local Government Board. The council has been established as the result of two previous conferences, at which it was resolved :—

> That a Central Council for London be established consisting of representatives of those engaged in district nursing and of others interested in the question, with the object of so systematising the arrangements for district nursing that there shall be adequate provision throughout the county.

There was a full attendance, including the President of the Local Government Board, Sir William Church, Sir Dyce Duckworth, Sir William Collins, Dr. W. J. Howarth, Dr. Lauriston Shaw, Dr. Christopher Addison, M.P., Mr. E. B. Turner, Dr. Martindale Ward, Dr. Major Greenwood, Dr. H. R. Carter, Dr. C. J. Harrison, and Dr. Charles Porter. After an introductory speech by Mr. Herbert Samuel, Sir William Collins was elected chairman and Dr. Addison vice-chairman of the council, and an executive committee of 25 members was appointed.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.—The inaugural meeting of this council was held at the house of the Royal Society of Medicine on Nov. 11th under the chairmanship of Sir Thomas Barlow, Bart., and a report of the proceedings appeared in THE LANCET of Nov. 14th. The provisional executive committee met on Nov. 23rd and directed that the minutes of the inaugural meeting should be circulated to all members of the National Council. In view of the amount of work which must be undertaken without delay in connexion with the present situation brought about by the war, the executive committee decided to appoint two subcommittees to endeavour to give immediate effect to the recommendations of the council. The honorary secretaries of the organisation are Dr. Douglas White and Mrs. A. C. Gotto, and the offices are at Kingsway House, Kingsway, W.C.

THE WAR.

THE KING AT THE FRONT.

The King spent nearly the whole of last week with his troops in France, and it is needless to say how much his visit was appreciated by all ranks of the Expeditionary Force and by the French and Belgian armies with whom they are coöperating. While in France His Majesty conferred decorations upon a number of officers, non-commissioned officers, and men, including several members of the Royal Army Medical Corps, whose names have appeared in official lists. The King also found time to encourage the medical personnel of the Expeditionary Force by making visits to many of the base hospitals, receiving hospitals and field hospitals, and showed his well-known keen insight into the details of hospital organisation and equipment, as well as his sympathy with the brave soldiers who are lying sick and wounded in a strange country.

THE DISTINGUISHED SERVICE ORDER.

To the list of officers of the Royal Army Medical Corps who have been appointed Companions of the Distinguished Service Order, in recognition of their services with the Expeditionary Force, published in THE LANCET last week, the following names are added:—

Lieutenant Henry Beddingfield:

For coolness and daring in repeatedly superintending removal of wounded from the firing line under heavy fire.

Major Sidney George Butler:

At Missy, on Sept. 15th. For coolness and courage in continuing all day to collect wounded under severe shell fire.

Captain Malcolm Leckie (deceased):

For gallant conduct and exceptional devotion to duty in attending to the wounded at Frameries, where he was himself wounded.

MENTIONED IN DESPATCHES.

The supplementary list of names to be added to those mentioned for meritorious service in Sir John French's despatch of Oct. 8th includes the name of Lieutenant H. Beddingfield, R.A.M.C.

Major-General Paris, commanding the Royal Naval Division, in his recently published despatch reporting the proceedings around Antwerp from Oct. 3rd to 9th, calls attention to the good services rendered, among other staff and brigade officers, by Fleet-Surgeon E. J. Finch, R.N.

CONSULTANTS TO THE FORCES.

Sir Berkeley Moynihan left for France on Dec. 4th to take up his appointment as Consulting Surgeon with the British Forces Oversea. Sir Bertrand Dawson, physician to the London Hospital, has entered upon his duties as additional Consulting Physician to the Forces, and Mr. W. T. Lister, ophthalmic surgeon to the London Hospital, has been similarly attached as Consulting Ophthalmic Surgeon.

THE CASUALTY LIST.

The following casualties among officers in the Royal Army Medical Corps and the Indian Medical Service serving with the Expeditionary Forces are officially reported:—

Killed: Major Pundit Piaraylal Atal, I.M.S., and Captain Kanwar Indarjit Singh, I.M.S.

Died of wounds: Lieutenant G. H. Chisnall, R.A.M.C.

Wounded: Major T. G. F. Paterson, I.M.S. (reported from the Persian Gulf).

Captain C. T. Edmunds, R.A.M.C., Captain F. T. Garland, R.A.M.C., and Captain E. M. Middleton, R.A.M.C., are reported through the United States Embassy to be prisoners of war.

Captain A. M. Pollard, R.A.M.C., and Captain H. G. Robertson, R.A.M.C., previously officially reported missing, are now unofficially reported prisoners of war.

CHOLERA IN CAMPS.

Experience has shown that cholera is one of the diseases liable to break out in camps or other gatherings where large numbers of men are crowded together in positions which have been chosen more for military than for hygienic reasons. The difficulty of adequately protecting sources of water-supply or providing proper latrine accommodation in such circumstances is obvious. The history of cholera during the recent campaigns in the Balkan peninsula is interesting in this connexion. Many thousands of cases occurred in 1912–13 in the Greek, Serbian, Bulgarian, and Turkish armies in the field. It is asserted that the infection was comparatively seldom waterborne, but was mainly spread by contact with persons suffering from the disease, or with infected articles, soil, or excreta. It is stated on good authority that the infection was commonly associated with dirty hands. Great difficulty was experienced in inducing recruits, especially in the Bulgarian army, to use the latrines provided for them, the men preferring to defæcate promiscuously in and around the camping-ground, the surface of which became in consequence greatly polluted with fæcal matter, some of it undoubtedly containing the specific vibrios of cholera deposited by convalescents or carrier cases. The excreta on the surface of the ground were trodden underfoot by many persons, and the boots of the soldiers were often coated with a mixture of mud and human fæces. On taking off their boots and nether garments the men's hands came in contact with this contaminated mud, and as opportunities for washing were seldom available, their meals were eaten with dirty and unwashed hands, the result being infection of the food. Though at the present moment there is, so far as we know, no cholera among the troops operating in Flanders or northern France, the possibility of the introduction of this disease cannot be lightly set aside, for the malady has been occurring in the eastern seat of war, in Galicia and other parts of Austria, as well as in Hungary. Austrian reinforcements, it is reported, have before now been sent to help the Germans in Belgium and France, and there is always the possibility of a cholera carrier being included in the drafts sent from eastern Europe to the west. If trenches occupied at one time by the Germans and Austrians were taken and reoccupied by the Allied troops it is possible that specific fæcal matter might be in these trenches. In that case the same method of contracting cholera that occurred in the Balkan camps might also easily occur in Flanders and northern France. But we know that sanitation is rigorously enforced in the British army, so that we have every reason to anticipate that the danger is reduced to the smallest dimensions. What applies to the diffusion of cholera in camps and trenches would apply equally well to the spread of enteric fever and dysentery in the same circumstances.

NEUROSES AND THE WAR.

It is no doubt somewhat early in the day to attempt to draw conclusions of wide applicability as to any connexion between the stress and strain of the war and the development of hysteria, neurasthenia, traumatic psychoneuroses, and so on. Nevertheless, those who are coming in contact with the nervous side of the cases retired from the war are beginning to notice the frequency with which hysteria, traumatic and otherwise, is showing itself, not only among the Belgians, but also in officers and men of our own forces. In many cases the agency of auto-suggestion can be clearly established. A Belgian soldier was hit on the back, low down on the left side, by a heavy wooden sleeper blown off a railway truck in the explosion of a shell; he was knocked down half unconscious from shock and pain combined, and eventually brought to this country with paralysis of the left leg, which on examination turns out to be a hysterical palsy of the left leg from the hip downward of classical type. Another Belgian was leaning his left shoulder against the parapet of a trench when a shell blew in the whole side of the trench, and he was partly submerged in a mass of earth and stones. He instantly felt numbness and weakness of the left side of the body, symptoms which are now found to be characteristically hysterical. A lieutenant in a North Country regiment was invalided back to the base with so-called dysentery, on recovery from which he noticed that his legs were weak and painful. A diagnosis of neuritis was made, but on reinvestigation at home he was discovered to be suffering from typical hysterical paraplegia. Another officer strained his right side in carrying an unusually heavy wounded man to a safe position behind the trenches. Three days later he observed that he was dragging his right foot and that his right arm was weak, and on coming under expert observation he was found to present the familiar signs of hysterical hemiplegia. Such cases as these and others that might be quoted present features not only of clinical interest but of scientific and theoretical importance. It is curious that the patients themselves admit that they were in excellent physical condition before the incidents occurred to which their illness is attributed, and that questioning fails to elicit any history of analogous or indeed any nervous symptoms in earlier years. It may be, of course, that the rigor of the campaign has influenced them more than could be suspected, and that the particular incident comes as an exciting cause. But not all cases can be thus explained. Even though we grant that auto-suggestion is at work, the question remains whether physical factors such as fatigue, hunger, the strain of responsibility and constant attention on the organs of special sense, repeated air concussion from high explosives, and so on, in some unrecognised fashion so impress the nervous system of those who apparently were entirely normal as to pave the way for the action of such a force as auto-suggestion. It is a matter, at least, for serious discussion. Again, it seems at present to be the case that traumatic hysteria is more common than traumatic neurasthenia, although in industrial cases the latter is probably the more frequent neurosis. It would be a mistake to conclude hastily from insufficient data, but in this connexion also there is matter for fruitful investigation at a later stage. A number of important considerations in this respect may be left aside for the present. The question of the influence of emotion in the development of hysteria has often been discussed. M. Babinski, it will be remembered, holds that hysteria never originates in emotion, and instances in support of his views the absence of hysteria after the severe mental strain produced in the inhabitants who suffered from the earthquakes at Messina. The data furnished already by four months' war suggest that these views require revision. An opportunity has arisen for the reinvestigation of these vital problems of nervous and mental disease of which competent and experienced observers, we are glad to think, are already fully availing themselves.

OBITUARY OF THE WAR.

EDWIN BEDFORD STEEL, B.A., M.B., B.CH. DUB.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

Major E. B. Steel, who died on Nov. 23rd from wounds received in action, was born in 1871 at Aldershot. He was educated at Rugby, where he won the "Crick" and was in the football XV., and at Trinity College, Dublin, and Dr. Steevens' Hospital, where he also distinguished himself as a footballer. He graduated M.B., B.Ch. in the University of Dublin in 1893, and joined the Royal Army Medical Corps in January, 1895, being promoted captain in 1898 and major in 1906. He served in India from 1897 to 1903, and again from 1907 to 1912, when he was made an Associate of the Order of St. John of Jerusalem in recognition of his services in connexion with plague duty. During the intervening period at home he was in command of a company at the Royal Army Medical Corps depôt at Aldershot, and qualified as a mental specialist. After his return in 1912 Major Steel was in command of the Higher Barracks Hospital at Exeter until the outbreak of war. He then went abroad in command of Field Ambulance No. 20, and was mentioned in dispatches for his good work at the army headquarters. At the beginning of October he was appointed Assistant Director of Medical Services attached to the 1st Cavalry Division. He was wounded by shell-fire on the morning of Nov. 23rd at La Clytte, and died that afternoon in Bailleul Hospital. Major Steel held the South African medal and the Durbar medal. He married in 1899, and leaves a widow, two sons, and a daughter. By his death the Royal Army Medical Corps loses a very able and devoted officer.

HUGH JOHN SLADEN SHIELDS, B.A., M.B. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant H. J. S. Shields, who was killed in action near Ypres on Oct. 20th at the age of 27, was the son of the Rev. A. T. Shields, rector of Thornford, Sherborne. He was educated at Loretto School, Jesus College, Cambridge, and the Middlesex Hospital, where he was a scholar and prizeman, and qualified at the Conjoint Board in 1912, obtaining his medical degree at Cambridge last year. He received his commission in the Royal Army Medical Corps in July, 1912, and was attached to the Irish Guards when war broke out. Shields was a fine oarsman and a man of outstanding character. He stroked the Cambridge University boat in 1910, won the Lowe sculls, and rowed in the winning international eight at the

Ghent regatta in 1911. In the retreat from Mons he was captured while carrying out his medical duties, but rejoined his battalion ten days later, to the great joy of the men, who were devoted to him. After many days further fighting he was shot while heroically tending the wounded under heavy fire in the course of an attack upon a German position in Belgium. The Officer Commanding the Irish Guards in the course of a letter to Lieutenant Shields's parents has written: "The way in which he insisted on attending to wounded men under fire was the admiration of all of us....... A better and braver man never was." His name has been mentioned in Sir John French's dispatches, and his early death, although exactly the end which he would have chosen for himself, is felt deeply by a wide circle of friends.

THE BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Dec. 5th states that the number of Auxiliary Home Red Cross Hospitals accepted by the War Office to date is 544, containing beds for 16,272, including 1424 beds accepted during the past week, and distributed among the Army Commands as follows: London, 877; Southern, 5092; Aldershot, 787; Eastern, 3831; Northern, 2565; Western, 2919; Irish, 201.

The arrangements in connexion with Lord Iveagh's generous offer to establish, equip, and maintain for a year a hospital of 200 beds at Netley have now been completed. It will be known as the "Irish Hospital" and will form an extension of the existing British Red Cross Hospital there.

A request having been received from the Director-General, Army Medical Service, through the Hon. Arthur Stanley that the Netley British Red Cross Hospital should be devoted entirely to the reception of Indian wounded; as a temporary measure preparations have been made to receive as many as possible. All the wards are now practically ready.

It is gratifying to record that the whole of the 1650 beds for the "King George" Hospital, London, have already been endowed, and a sum of £41,250 has been received under this heading alone.

THE SECOND GENERAL EASTERN HOSPITAL (TERRITORIAL), BRIGHTON.—A medical correspondent sends the following notes of some interesting cases admitted from the front:—*Some cases of secondary hæmorrhage.*—Cases of secondary hæmorrhage have not been common. Of about 1000 men from the front, so far only eight cases have occurred. All followed bullet wounds, in one case of the upper part of the thigh, with secondary hæmorrhage from the external pudic artery, which was treated by ligature of the bleeding artery in the wound; a second in the lower part of the thigh, the anastomotica magna being the vessel affected. This was treated in a similar manner. The third case was a much more serious one; it was from the axilla, following a compound comminuted fracture of the upper end of the humerus. A large subcutaneous swelling very suddenly appeared under the pectoral muscles. This was incised, but it was found impossible to ligature at the bleeding point, and the subclavian artery was accordingly tied. All went well for about ten days, when hæmorrhage again occurred and was repeated on several occasions. To save the man's life it was decided to disarticulate the arm at the shoulder-joint. He is now doing quite well. The fourth case was that of a man who was shot through the palate, and who had severe bleeding from a palatine vessel some ten days later, on the separation of a large slough from the palatal wound. This was easily controlled by pressure, but the patient was in an exceedingly weak and emaciated condition on admission, and died a few hours later from exhaustion. The fifth case was that of a man with a shell wound of the right groin penetrating the bowel. In this man the piece of shell passed through the right groin, and lodged in the right iliac fossa, wounding the bowel. Fæces discharged through the opening in the groin, and brisk hæmorrhage occurred from the wound. This was opened up freely and the bleeding vessel, which was the circumflex iliac, was ligatured, the wound being left open and packed with gauze. A large piece of shell casing was removed from the wound, and the patient is doing well.

In another case a man received a bullet wound of the knee-joint. This suppurated profusely. He was suddenly seized with terrific secondary hæmorrhage from the popliteal artery. A tourniquet was at once applied and amputation at the lower end of the femur carried out. A seventh example is that of a wound of the arm, in which the bleeding was not from the main vessel, but from a branch, and was easily controlled. In the last case the wound was from a shrapnel bullet entering directly backwards just above the centre of the clavicle, which was broken in the middle into several pieces. There was a large sinus about an inch in diameter passing backwards. Secondary hæmorrhage, not extensive, occurred on several occasions, probably from the transversalis colli artery. This was easily controlled by pressure. It is hoped that, on removal of the bullet, treatment of the wound by peroxide irrigations will cause the sinus to close.

Bullet wound of kidney.—A bullet passed right through this man's abdomen, from front to back, and was followed by hæmaturia which lasted for five days and then ceased. No other symptoms were produced. This is a good example of the way in which a bullet will pass through a cavity containing delicate and important structures like the intestine without doing any damage to them.

Three cases of tetanus.—The first case was that of a man admitted for bullet wounds received at Ypres. His condition was as follows. In the right thigh there was a gutter wound four inches long and one inch broad, in the right arm a wound about two inches in diameter, and in the right axilla a ragged wound about one inch across. He appeared to be doing all right, when on the tenth day after his injury he complained that he felt stiff and that he could not open his mouth. 1000 units of antitetanic serum was at once injected and chloretone was administered, but in spite of this treatment and the repetition of antitoxin he died in about 48 hours. The second case was that of a man wounded in the forearm. When he arrived at the hospital his splints and bandage were removed. They had been on three days and no opportunity had occurred for dressing him during his transport. The arm was found to be gangrenous and was amputated. Tetanus developed two or three days later—i.e., about ten days after he had been wounded—and in spite of tetanus antitoxin and chloretone he died. The third case was very similar. A bullet wound of the arm followed by the development of tetanus in about ten days, the employment of chloretone and antitoxin, and death. This man had recovered from an attack of tetanus about ten years ago, following a bullet wound received in India. These cases seem to support the generally accepted view that tetanus with a short incubation period—i.e., less than 12 days—is a fatal disease in spite of the use of tetanus antitoxin.

Some bullet wounds of the brain.—Shrapnel bullet wound of skull. Depressed fracture. Cerebral irritation. Trephining. This man was shot in the head, the bullet causing a gutter wound of the back of the vertex three inches long. It had been sewn up at the French base hospital. On admission it was found to be suppurating and was opened up. It was then discovered that a piece of shrapnel remained in the wound, and that there was a fracture of the skull beneath. A few days later—about a fortnight from the receipt of the injury—signs of cerebral irritation (i.e., irregular pyrexia, somnolence, slow pulse, slight optic neuritis, &c.), manifested themselves. The patient was anæsthetised and the wound opened up freely. Several loose fragments of bone were removed. One of them, a triangular piece with a length of about half an inch each way, had been driven through the dura mater into the brain. The bone was chipped away all round, the loose pieces removed, and the wound left well open for drainage. The patient is doing well.

In a case of bullet wound of the brain there was a depressed fracture of the occipital region of the brain, which was opened up. An abscess, deeply seated, was found, with some loose fragments of bone. This was drained, and with the exception of some hemianopia, the patient has quite recovered. No trace of a bullet was found and none could be seen by X ray examination. Was it embedded deeply in the base of the skull, or had it struck the bone obliquely, glancing off and driving the fragments of bone in the brain in its flight?

Wound of bowel through the back.—Here there was a wound of the lumbar region which became inflamed and through which gas and fæces escaped. No treatment beyond the application of antiseptic dressings was carried out, but the wound healed well. This is a good example of the "wait-and-see" policy of bullet wounds of important cavities.

Wound of the interscapular region and neck.—In this case the wound of entry was in the interscapular region, that of exit by the side of the thyroid cartilage. Beyond the presence of a little fluid in the pleural cavity no mischief was done—an excellent instance of the curious way in which a bullet passes near many important structures without doing any damage to any of them.

A case of facial paralysis following concussion from the explosion of a shell.—In this case the man had well-marked facial paralysis on the right side due to the explosion of a shell. No part of the shell struck him, but the general shock and concussion caused paralysis of the seventh nerve. He was also deaf on the same side, but this was probably due to his ear being blocked with wax or débris. There have been many cases of concussion of nerves due to the passage of bullets through limbs, causing paralysis, loss of sensation, &c., without any actual lesion of the nerve. This has been noticed especially in the arm. They have recovered in quite a short time. Much more difficult are those cases in which recovery is delayed, and in which it seems impossible to make an accurate diagnosis between concussion and an actual lesion of the nerve.

Some fractures of the jaw.—Explosive wound of the lower jaw. A man was shot in the face, the bullet entering at the left angle of the mouth, slightly grazing it, cutting off the tip of his tongue, and making its exit through the ramus of the lower jaw. The wound was a large one, three inches by two, lacerated, septic, discharging profusely, and showing a detached piece of exposed bone, a regular "explosive wound," and one of those so often wrongly attributed to dum-dum bullets. The wound is cleaning nicely after the employment of peroxide irrigations and chlorinated soda dressings. This is an excellent method of cleansing foul wounds, and is being largely used in this hospital now. A splint is being made for this man to keep his teeth and the fragments of the bone in as good a position as possible. In another case a bullet entered through the right cheek, passing through the right upper jaw and out through the mouth, which must have been open, as no wound was caused. The wound was very septic, but has improved very considerably since admission. This case has been treated on the verandah, and probably the free exposure to fresh air has, as in most septic wounds, contributed largely to the marked and rapid improvement. In a third example a bullet entered through the body of the lower jaw and remained embedded in the middle of the tongue—a most unusual position for a missile to lodge.

Two cases of aneurysm.—In the first case the patient had a traumatic aneurysm of the first part of the axillary artery; in the second case the aneurysm was of the brachial artery. In both instances the treatment undertaken was the same—namely, cutting down on the aneurysm and ligature of the vessel above and below.

An example of temporary burial alive.—The following is an interesting case and also quite unusual. Five men were in a trench when a German shell exploded, destroying the trench shelter. Three were killed, a fourth wounded, and the fifth buried completely under the earth. Fortunately a plank fell over his chest and, to some extent, protected him from crushing. He was buried alive for four hours, and when finally dug out he had just lost consciousness. He soon recovered and went back to fight in the trenches, but unfortunately in the accident he had lost his false teeth, and was therefore unable to masticate or digest his food. As a result he became ill, and was sent home for the purpose of obtaining a new denture. This story illustrates the importance of a good set of teeth for a man on active service. Three other cases in the first convoy of 47 admitted to the Kemp Town branch of the Brighton Hospital had been invalided home for exactly the same cause—namely, inability to masticate and digest the field food of the army on account either of lack or decay of teeth.

A man with complete loss of memory.—A man was admitted who had lost his memory. The only things he knew when admitted were his name and regiment. There was no sign of injury and no history whatever. No one knew anything about him, and one can only speculate that he received some very severe shock which has caused him to get into this condition.

Pickaxe wound of arm.—This very unusual method of producing a wound was due to the accidental infliction of a stab from a pickaxe by a comrade in the trenches. There was a punctured wound of the upper arm, which was profusely suppurating. It was treated by peroxide irrigation, and as it had most certainly been contaminated by earth he was given a prophylactic dose of antitetanic serum. Large numbers of cases of wounds have received this prophylactic injection before admission to hospital, in some instances even on the field.

Extensive flesh wounds.—Numbers of examples of large flesh wounds have been met with. For instance, one man had two large shrapnel injuries in the legs, one in the back part of the left thigh, a large foul wound, 12 inches by 6, and another slightly smaller on the back of the right calf. The improvement under treatment (peroxide washings, chlorinated soda dressings, with rest, good food, and fresh air, an ideal treatment for septic wounds) was very marked and immediate. Scarlet-red ointment is being applied to wounds of this description when they lose the foulness which they so often present on admission.

Some wounds of the eyeball.—There have been a few cases of wounds of the eyeball. In one man the left orbit was badly damaged and the eyeball lacerated by a bullet. This was removed in France. Strangely enough, up to now the man has no idea that he has lost his eye. Was it an eye blind or practically blind before injury, so that he does not miss it? In another instance a man had a scalp wound and a traumatic cataract, probably due to the penetration of a minute fragment of shrapnel. As there is in all likelihood a foreign body in the eyeball, an X ray examination is being made, and the eye will be removed if necessary. Another man had a small penetrating wound of the cornea, causing traumatic iritis, with anterior synechia, and cataract. A fourth case presented a gutter wound of the outer side of the orbit, followed by a good deal of chemosis of the conjunctiva. The eye was quite blind, although there was no obvious lesion. Query, was this due to concussion of the optic nerve?

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE.—A meeting of this committee was held in the hall of the Royal College of Physicians of Edinburgh on Dec. 5th, when there were present the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the President of the Royal Faculty of Physicians and Surgeons of Glasgow, the Deans of the Faculties of Medicine of Glasgow and Edinburgh Universities, and Dr. Ashley W. Mackintosh, representing the Dean of the Faculty of Medicine of Aberdeen University, Dr. J. C. McVail, Dr. J. R. Currie, Dr. J. Stevens, and Dr. Norman Walker (convener). The convener reported that there had been numerous applications to the committee for assistance in procuring locum tenents, and many offers of service from practitioners retired or temporarily unemployed. Though they had not been able to provide direct supply in all cases the influence of the committee had been of considerable value in promoting arrangements for the carrying on of the work of the men on service, while the recommendation of the committee that 5 guineas should be the maximum fee charged to men serving with the colours had apparently been loyally accepted. From several communications he had received it was evident that the financial arrangements between the men called out and their neighbours who were doing their work were not always satisfactory, and indeed in many cases no arrangements at all had been made. It was remitted to a subcommittee to consider whether it would be advisable to issue a series of model arrangements suitable to different varieties of practice which might help in averting difficulties that might arise, and to advise on any cases of immediate difficulty brought under the notice of the convener. It being evident that more men would before long be called out, the committee decided to make a fresh appeal for assistance to medical men and women who were in a position to help. A suggestion that the convener should address a meeting or meetings on the work of the committee was approved.

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that the reserve unit of the North Midland Mounted Brigade Field Ambulance is in urgent need of four medical officers. Applications should be made to the Officer Commanding Reserve Unit, North Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps (T.F.), the Drill Hall, Nineveh-road, Handsworth, Birmingham. The pay as lieutenant is 14*s.* per diem, with 2*s.* for food allowance and 3*s.* for billeting expenses when necessary. £30 are allowed for uniform and £7 10*s.* for field equipment.

NURSING IN AUXILIARY HOSPITALS.—A resolution was carried unanimously at the annual meeting of the National Council of Trained Nurses of Great Britain and Ireland, held in London on Dec. 3rd, placing on record unqualified disapproval of the present organisation of the nursing of sick and wounded soldiers in military auxiliary hospitals at home and abroad. The Council, holding the opinion that the standard of nursing for the sick and wounded should be of the highest quality, earnestly petitions the Secretary of State for War, whose department is primarily responsible for the health and comfort of the troops, to prevent the expenditure of the munificent subscriptions of the public on inefficient nursing and the subjection of the sick and wounded to the dangerous interference of untrained and unskilled women, who have been placed in positions of responsibility for which they are not qualified, greatly to the detriment of the discipline in military auxiliary hospitals and the general welfare of the sick. The resolution has been sent to the Secretary of State for War.

THE BRITISH FIELD HOSPITAL FOR BELGIUM.—Since this hospital left Antwerp on the fall of that city it has been established at Furnes (between Dunkirk and Dixmude) under the immediate control of the Belgian Minister for War, and has been frequently visited by the Queen of the Belgians, who is its patron. The hospital is now under the direction of Mr. W. S. Perrin, until recently surgical registrar at the London Hospital, who is assisted by a staff of 7 surgeons and 22 trained nurses. A sum of £20,000 is needed for the efficient working of the hospital, which during the past month treated 1000 cases, and subscriptions are invited by the secretary, 21, Suffolk-street, Pall Mall, London, S.W.

EDINBURGH INDIANS' AMBULANCE CORPS.—The Edinburgh University Indian Field Ambulance Corps sent its second detachment on Dec. 6th from Princes-street station to New Hut Hospital, Brockenhurst. It comprised 13 subordinate officers: Corporals M. J. Khan and R. K. Syed; Lance-Corporals G. C. Sahgal and J. Lalthoo; and Cadets S. M. Dastgir, I. A. Shah, A. M. Ghosh, P. K. Ghosh, S. N. Seal, N. P. Singh, Y. Jan Kieam, G. Auditto, and B. P. Varma.

Sir Charles Ball and Sir Thomas Myles have been appointed consulting surgeons to the troops in Ireland, with the temporary rank of lieutenant-colonels in the Army Medical Service.

Sir James Mackenzie Davidson has lately been working upon an adaptation of the "telephone probe" which he devised 30 years ago for the localisation of metallic foreign bodies. The present modification is quite simple in use and has already been found of practical service at the time of operation, after the bullet or piece of shrapnel has previously been located by means of the X rays.

THE special exhibit of interesting objects and relics associated with naval and military surgery, nursing, and ambulance, which has been in course of arrangement at the Wellcome Historical Museum, 54A, Wigmore-street, London, W., will be on view from Monday next, Dec. 14th.

NEWTON ABBOT VOLUNTARY AID HOSPITAL.—The Newton Abbot (Devon) Voluntary Aid Hospital has been recently opened for the reception of patients, and now accommodates 45 wounded soldiers. The institution contains ten wards, operating room, X ray apparatus, &c. The hospital stands on an excellent site, and the grounds will be much appreciated by the patients. The medical staff consists of Dr. J. Culross, Mr. R. H. Grimbly, Dr. R. F. Higgin, and Dr. W. Patey.

Medical News.

UNIVERSITY OF OXFORD: DIPLOMA IN PUBLIC HEALTH.—The following have satisfied the examiners in the recent examination for the Diploma in Public Health (D.P.H.):—

Parts I. and II.—G. B. D. Adams.
Part I.—T. R. Bowen and A. E. A. Carver.
Part II.—F. S. Carson.

UNIVERSITY OF CAMBRIDGE.—The State Medicine Syndicate have appointed Dr. Henry Head, Trinity; Dr. Maurice Craig, Gonville and Caius; and Dr. W. H. R. Rivers, St. John's, to be members of the managing committee for the University Diploma in Psychological Medicine, to hold office for three years.—Dr. G. S. Graham-Smith has been appointed a member of the M.D. Degree Committee until Feb. 28th next in place of Dr. W. E. Dixon, who is now assessor to the Regius professor of physic.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 28 cases were considered and grants amounting to £278 4*s.* voted to 26 of the applicants. An annuity of £20 was also made to one of the applicants. The following is a summary of the cases relieved:—

Daughter, aged 55, of M.R.C.S. Eng. who practised in Wiltshire and Devon. Late husband had been helped by the Fund, and on his death in June this year left his widow entirely unprovided for. Sister has helped her a little, but cannot continue to do so. One daughter, unable to help. Voted £12 in 12 instalments.—Widow, aged 69, of M.R.C.S.Eng. who practised in London, died in 1913, and left his widow totally unprovided for. Had commenced a boarding house, but was seized with aphasia and unable to carry it on. Made an annuitant of £20 and the Guild to try to get her into a home.—Widow, aged 65, of L.R.C.P. & S. Irel. who practised at Catford and Southend. Too old to work. Lives with a son and his family, who cannot afford to keep her. Has an Epsom pension. The case strongly recommended by the Guild visitor. Relieved twice, £18. Voted £12 in 12 instalments.—Daughter, aged 71, of M.D. Lond. who practised in North London. Unable to work owing to defective eyesight. Has recently obtained an annuity from another society. Proposes to apply for the Old Age Pension. Voted £2.—Widow, aged 51, of M.D. Edin. who practised at Newcastle-on-Tyne. Has C.M.B. certificate and earned a living by nursing, but fractured her leg some time since and is making very slow progress. A little help from a married daughter, but not enough to keep her. Voted £12 in 12 instalments.—Widow, aged 55, of M.D. Aberd. who died in 1904 and practised at Balham. Lost the little money left her by husband in assisting her only son, a mining engineer, in South Africa. The venture was a failure, and the son has joined the South African army. Qualified mental nurse, but finds difficulty in obtaining work on account of age. Voted £10 in two instalments and referred to the Guild.—Widow, aged 59, of L.S.A. Lond. who practised at Oldham and died in 1898. Youngest son, who has in the past entirely supported her, has joined the army, and up to the present has not had maintenance allowance. Two other children unable to assist. Voted £5 and recommended to apply to the Prince of Wales Fund.—Son, aged 18, of L.R.C.P. & S. Edin. who is also a recipient of the Fund. Assistance wanted for completion of education as a dentist. The case recommended by the Glasgow Branch of the Guild, and the current fees wanted £13 13*s.* The Guild undertook to provide £9 9*s.* and the Fund £4 4*s.*—Daughter, aged 55, of M.R.C S. Eng., who practised at Liverpool. Suffers from asthma and internal trouble and unable to work. Uncle pays rent, but otherwise no income. Previous relief five times, £56. Voted £12 in 12 instalments and referred to the Guild.—Widow, aged 59, of M.R.C.S. Eng. who practised at Liverpool. Has endeavoured to earn a living by nursing, but only earned £19 this year. Age makes it difficult to obtain patients. Relieved five times, £25. Voted £12 in 12 instalments and referred to the Guild.—Widow, aged 56, of L.R.C.P. & S. Edin. who practised at Grantown, and died in 1913 and was a recipient of the Fund. Five children, all at school. Endeavours to earn a living by taking in boarders, but cannot make sufficient to support the family. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 63, of F.R.C.S. Eng. who practised at Chester. Acts as housekeeper when able to obtain posts, but has been unsuccessful of late. Relieved twice, £12. Voted £10 in two instalments.—Widow, aged 77, of M.D. Lond. who practised in London. Suffers from rheumatic gout in hands and feet. Only income two small annuities. Relieved seven times, £35. Voted £10 in two instalments.—Daughter, aged 48, of M.R.C.S. who practised in India and London. Unable to work owing to nervous breakdown. Only income £23 per annum from investments. Relieved once, £5. Voted £5 in one instalment and referred to Guild to see if they can assist her to have her teeth attended to.—Daughters, ages 62 and 56, of M.R.C.S. Eng. who practised at Bexley Heath. They try to obtain a living by needlework, but so far this year have only earned £6 5*s.* Only other income £20 from a friend. Previous relief ten times, £154. Voted £20 in 12 instalments.—Widow, aged 67, of L.R.C.P. Edin. who practised at Cardiff. Health very bad. Only income £24 per annum from another charity. Previous relief nine times, £66. Voted £12 in 12 instalments.—Wife, aged 48, of M.R.C.S. who practised at Chesham, but deserted her in 1905. Three children, the youngest at Epsom and others at school. Health very unsatisfactory and eyesight defective. Only income about £24 per annum. Previous relief, £12. Voted £12, with leave to apply again and referred to Guild.—Widow, aged 56, of L.R.C.P. Edin. who practised at Langley. Endeavours to earn a living by taking in paying guests, but unsuccessful of late. Lives in own house, but it is mortgaged. Relieved four times, £40. Voted £10 in two instalments.—Daughters, ages 55 and 64, of an M.D. who practised in Cornwall. They both have poor health, but try to earn a living by taking in paying guests, but this year has been very bad. They live in own house. Relieved five times, £82. Voted £18 in 12 instalments.—Widow, aged 76, of M.R.C.S. Eng. who practised at Holderness. Health very bad. Has six children, 30 to 53, but they are unable to assist. Takes in lodgers when she can get them, but too old to do much. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 54, of L.S.A. Lond. who practised at Islington. Practically blind, and her youngest son, who practically supported her, has just joined the army. Her other son, married, unable to help. Relieved ten times, £64. Voted £18 in 12 instalments.—Daughter, aged 60, of L.S.A. Lond. who practised at Longton. Is suffering from spinal curvature and internal trouble. Only income £25 per annum and a little help from the Guild. Relieved 14 times, £152. Voted £18 in 12 instalments.—L.R.C.P. & S. Edin., aged 57, who practised at Old Kilpatrick. Suffering from spastic paralysis and unable to work. Lives with sister who keeps a boarding-house. One son, aged 18, whom the Fund and Guild are helping to educate as a dentist. Relieved ten times. £120. Voted £12 in 12 instalments.—Widow, aged 63, of M.R.C.S. Eng. who practised at Highgate. Has been ill some months and recently operated on for uterine fibroids, and suffers from rheumatism. Has earned a living by dressmaking. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 62, of L.R.C.P. & L.S.A. Lond. who practised at Brixton. Unable to earn own living owing to deafness and ill-health. Only income a little from sister. Relieved nine times, £104. Voted £12 in 12 instalments.—M.R.C.S. Eng., aged 80, who at one time practised at Great Yarmouth. Advanced age prevents him from working; has an Epsom pension and occasionally obtains an appointment as ship's surgeon. Relieved three times, £36. Voted £12 in 12 instalments.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

Sir George Birdwood, K.C.I.E., M.D., the Anglo-Indian veteran, celebrated the eighty-second anniversary of his birthday on Tuesday last.

Irish Women's National Health Association.—The annual meeting of the Women's National Health Association was held last week in Dublin. Reports were made of the various activities in which the association has been engaged. It was stated that 1739 patients had been treated at Peamount Sanatorium in the two years of its existence and 229 at Rosslare.

Royal College of Physicians of Ireland.—At the last monthly meeting of the Royal College of Physicians of Ireland held on Dec. 4th a presentation was made to the College by Miss Gerrard of a portrait of Dr. Jonathan Osborne, who was President of the College in 1834-35, and was for several years one of the King's professors in the School of Physic. Dr. James Little, senior Fellow of the College, and one of the last surviving of Osborne's pupils, made the presentation on behalf of Miss Gerrard.

Royal College of Surgeons in Ireland. Students' Union.—The inaugural address to the Students' Union of the Royal College of Surgeons was given on Dec. 3rd by Mr. T. E. Gordon, F.R.C.S. Irel., who chose as his subject "The War." His lecture was chiefly directed to the members of the union who had joined or were about to join the colours. It was stated that already more than 400 alumni of the College were on service. An interesting discussion followed, in which the Lord Mayor of Dublin, General Friend, and Mr. Justice Barton took part.

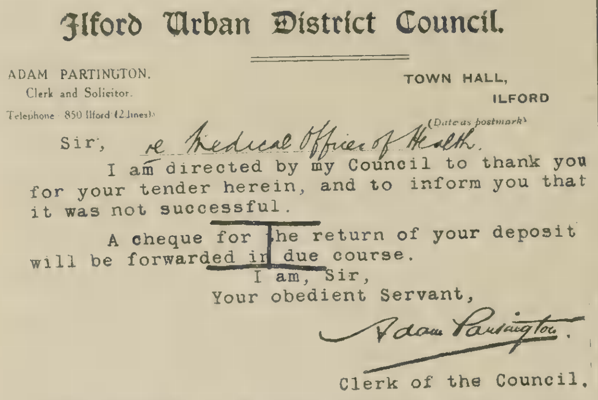
N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

OFFICIAL MANNERS.

OUR readers may remember the circumstances in which the Ilford urban district council, after many endeavours, succeeded at last in getting rid of its medical officer of health; we referred to the matter on several occasions and expressed our opinion of this local authority's attitude and behaviour. A correspondent now sends us the postcard, which we reproduce below in facsimile, omitting only the name of the medical man to whom it was addressed. Our correspondent explains that this postcard sent through the ordinary post with a halfpenny stamp was the only acknowledgment made by the Ilford urban district council of an application for the vacant medical officership of health.



Ilford Urban District Council.

ADAM PARTINGTON.
Clerk and Solicitor.
Telephone 850 Ilford (2 lines).

TOWN HALL,
ILFORD

(Date as postmark)

Sir, re Medical Officer of Health.

I am directed by my Council to thank you for your tender herein, and to inform you that it was not successful.

A cheque for the return of your deposit will be forwarded in due course.

I am, Sir,
Your obedient Servant,
Adam Partington.
Clerk of the Council.

At the request of the council the candidate had sent to a list of councillors provided for that purpose some 25 printed copies of his application for the post, costing him upwards of £2. It will be noted that the card (which is printed in imitation typewritten characters with a facsimile signature) is really a form of rejection of a tradesman's tender for supplies, which has very crudely been made do duty in another capacity. Apart altogether from the question of taste, the receipt of such a card through the open post might conceivably be most embarrassing to an unsuccessful candidate. Nevertheless, as our correspondent hastens to add, his own personal feeling is one of relief at not being appointed to serve a body which exhibits such methods of economy.

VIRCHOW AND THE WAR.

To the Editor of THE LANCET.

SIR,—Nearly 20 years ago the following paragraph was published in an annual widely read by the French people. It would be interesting to see how far Virchow's prognostications will come true in the present upheaval.

"Désarmer ou périr : tel est, pour les nations européennes, le terrible dilemme qui s'impose aujourd'hui.

"Les armements poussés sans trêve ni repos, c'est le microbe de la guerre semé à pleines mains et sans discontinuité. Car plus le voisin voit le voisin armer, plus il se croit dans l'obligation d'armer lui-même. Et cette course effrénée au clocher des armements (c'est: au clocher de la mort qu'il faudrait dire) continuera ainsi jusqu'à l'exténuation, jusqu'à l'épuisement des forces, jusqu'à l'extinction de la vie. Je me trompe. Lorsque les gouvernements verront la vacuité effroyable de leurs coffres-forts, et qu'ils se rendront compte de l'impossibilité de pouvoir les remplir à l'aide de nouveaux impôts—toutes les ressources étant taries et la capacité impositive de leurs pays respectifs réduite à néant—ils se précipiteront à corps perdu dans la guerre, avec l'espoir de sortir enfin d'une situation sans issue.—Dr. Virchow."

I am, Sir, yours faithfully,
London, Dec. 8th, 1914. A. S. F.

POCKET HEATERS.

To the Editor of THE LANCET.

SIR,—I read last week that the latest German recruits had been supplied with pocket electric radiators for warming purposes, but I understand that such an apparatus would require constant recharging, the facilities for which would often be impossible to obtain in the fighting line. A day or two ago I read in an article in a lay paper that a retired Russian colonel had recommended a pocket heater used by the Russian troops. I see it is now advertised under the name of the Kyron heat-giver. A few years ago the "Instra" pocket warmer, which was practically on the same principle, was introduced into this country. The stick of fuel in these heaters is apparently some kind of carbon wrapped in paper. These pocket radiators are of Japanese origin, and I first saw them about 25 years ago, when they consisted of a most gaudy highly-coloured box for the pocket or muff, and they then attracted attention as a curious novelty from the Far East; they were looked upon more or less as an ingenious toy, but they have since been improved. A thick slab of glass heated up makes a clean heater and retains heat well, although it is not easy to get a slab which will stand the heat without cracking after a time. A small solid cube of steel heated on the fire-bars and dropped into a small tobacco or mustard tin will make a heater sometimes too hot to hold and will last an hour. It is on the principle of the Russian tea-urn or "samovar," where the red-hot block of metal or carbon is dropped into the middle of the tea-urn in a compartment made for it.

I am, Sir, yours faithfully,
London, Dec. 8th, 1914. X. Y. Z.

INSURANCE ACT PRESCRIBING.

THE Forfarshire Local Medical, Panel, and Pharmaceutical Committees have issued a useful little pamphlet entitled "Official Rules for Prescribing and Formulary," which is marked "For private circulation only," and yet is priced at 1*s*. The rules, which appear to have been drafted in consequence of the great increase in the drug bill for the area, have been devised to check excessive or reckless prescribing as a result of a complete scrutiny of all the Insurance Act prescriptions during three months. From this it was found that a considerable portion of the charges upon the drug fund could have been avoided without loss of efficiency and even with advantage to insured patients by properly directed economy in prescribing. Particular points worthy of notice in these rules are a total prohibition of patent or secret medicines, and the use of corresponding official drugs and preparations in place of proprietary articles where possible. A list of such corresponding drugs and official formulæ for proprietary articles is appended, as well as a stock preparation pharmacopœia of the usual hospital type.

THE CHILDREN'S DINNER FUND.

A BAZAAR in aid of the Children's Dinner Fund, promoted by the London Vegetarian Association, will be opened at the Memorial Hall, Farringdon-street, E.C., to-day, Saturday, Dec. 12th, at 3 P.M., by Mrs. Despard. There will be an exhibition of food, and cookery demonstrations will be made, including the use of the Hay box or fireless cooker.

THE AFTER-CARE ASSOCIATION.

THE After-Care Association for Poor Persons Discharged Recovered from Asylums for the Insane earnestly appeals for funds to carry on and extend its work. The association, which is the only one of its kind in the United Kingdom, assists cases in all parts of the country in various ways. Secretary: Mr. H. Thornhill Roxby, Church House, Westminster, S.W.

UP-TO-DATE SPELLING.

FROM a second-hand bookseller's catalogue: "...... This work is an extremely rare one, and it is upon it that the present translation is based; considerable alterations and (it is hoped) improvements have however been made, and *antiquated authography* has been corrected."

HELICON.

WE have received from the Castle Laboratory, Jeffreys-place, London, N.W., a sample of Helicon tablets, each containing 5 grains of pure acetyl-salicylic acid. It is, we are told, "entirely British manufactured," and conforms, we find, with the standards of purity laid down in the British Pharmacopœia, 1914.

◆

C. T.—Our correspondent will find the following references in THE LANCET to the use of iodine for wounds in war time. August 17th, 1912 (p. 463), abstract of a paper read in the Navy, Army, and Ambulance Section of the British Medical Association meeting on The More General Use of Iodine in First-Aid Treatment of Accidental Wounds. Clinical Note, by Mr. Edmund Owen, F.R.C.S., in THE LANCET of Oct. 11th, 1913 (p. 1063), on Tincture of Iodine as a Household Remedy for Wounds and Skin Surface Cleaning. Letter in THE LANCET of Jan. 3rd, 1914 (p. 75), on Iodine in the Dressing of Wounds (Experiences in the Balkan War).

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, Leonard G. Guthrie): at 5 P.M.

Papers :

Dr. George Peachey: A Seventeenth Century Medical Superstition.

Mr. C. J. S. Thompson: The Apothecary in England from the Fourteenth to the Sixteenth Century.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.):

Dr. Knowsley Sibley: Case of Angiokeratoma.

Other cases will be shown.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Paper:—Mr. J. E. Barnard: X Rays in Relation to Microscopy.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Paper:—Dr. A. Balfour: Tropical Problems in the New World (illustrated by slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

TUESDAY.—5 P.M., Bradshaw Lecture:—Sir Frederic Eve: Acute Hæmorrhagic Pancreatitis, with Remarks on the Etiology of Chronic Pancreatitis.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Croonian Lectures

ON

MODERN ASPECTS OF CERTAIN PROBLEMS IN THE PATHOLOGY OF MENTAL DISORDERS.

Delivered before the Royal College of Physicians of London,

BY EDWIN GOODALL, M.D. LOND., B.S., F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, CITY OF CARDIFF MENTAL HOSPITAL.

LECTURE III.[*]

SIR THOMAS BARLOW AND GENTLEMEN,—Continuing my observations upon leucocytal counts in the psychoses which, by reason of their clinical manifestations, afford ground for inquiry as to a possible toxic origin, I submit to you eight records of quantitative and qualitative counts in cases of dementia paralytica.

Variations of Leucocytal Count in Dementia Paralytica.

In each case these cover a considerable period of time. I would here express my obligations to my colleague, Dr. D. L. Jackson, formerly assistant physician at the Cardiff Mental Hospital, for valuable assistance in carrying out these counts, as well as those which I presented at my last lecture. The object of these observations was more particularly to ascertain whether the qualitative leucocytal count in a remission of the disease, or in a period of obvious quiescence, differed from that observed in the active phases or at times of exacerbation. The cases I have selected comprise the best material at my disposal during the past three years; they include only one in which a remission of the disease was so pronounced and established that the patient was able to return home for a period. From my experience I should say that a remission of this kind is extremely rare amongst the rate-supported classes, and I therefore trust that some of my colleagues whose work lies amongst patients in registered hospitals or private asylums may be able to repeat and amplify these observations. Copies of my records are before you, and I need only refer briefly to the cases.

[Here the lecturer pointed out the variations in the qualitative cell counts, associated with clinical variations, as illustrated in the records of which the following (Table XI.) are a few.]

In addition to illustrating the point that an absolute and relative lymphocytosis is present in states of remission and of marked quiescence in dementia paralytica, to be replaced by polynucleosis on the occurrence of exacerbations (such as seizures, febrile states of unknown causation), the accompanying records show that the total count does not regularly vary with variations in the clinical condition, although it usually does, and that the total count is moderately high during remissions and states of quiescence. The variations that take place in the leucocytal count, with clinical variations, are rather qualitative than quantitative. Further, it appears that eosinophiles are either absent or in an extremely low proportion in these cases at all times except during remission, and even then the proportion is low. This remark applies to all the cases illustrative of different kinds of insanity of which I showed charts at my last lecture.

Summary of Observations on the Leucocytal Count.

If, now, I may extract summarily the salient points of the observations of many workers, several of whom I have quoted from, upon the leucocytal count in the psychoses which are *primâ facie* toxic in origin, I think the evidence furnished (leucocytosis, neutrophile increase) is in favour of toxæmia, not a grave toxæmia; this accords with the general clinical evidence. There is also evidence of a lymphocytal reaction in dementia paralytica, broken by a neutrophile predominance with exacerbations. We know that in various diseases of parasitic origin, such as typhoid fever, secondary and tertiary syphilis, trypanosomiasis, and others presumably parasitic, such as measles, mumps, there is a lymphocytosis; and there seems ground for the belief that this form of white cell reaction, and for the same reason (parasitic causation), is characteristic of dementia paralytica also. If in "florid" states, and in states of exacerbation of various kinds, the predominant reaction is neutrophile, that may be merely because "intercurrent" non-specific toxic agencies are operative. According to this argument such states and such reaction are superimposed merely. This hæmatological observation in respect of the prevalence of lymphocytes in dementia paralytica is a corroboration of a similar one referred to in an address I delivered in Birmingham in 1911,[1] and constitutes clinical evidence, as far as it goes, of the presence of a parasite such as the treponema. Our present information points to an absolute and relative lymphocytosis not of a pronounced kind, as the characteristic condition in the states grouped under the head of "dementia præcox," after the initial stages have passed, and in subacute and chronic mania and melancholia. The significance of this is obscure.

FERMENTS AND ANTIFERMENTS.

During 1913 a considerable amount of work has been carried on in Germany in the domain of psychiatry with the methods introduced by Abderhalden to demonstrate the presence of specific ferments in the blood serum. Fauser[2] was probably the first to apply these tests in mental disorders, and his results have been in the main confirmed by subsequent observers. The evidence is now appreciable to the effect that in dementia præcox breakdown products of the protein of the cerebral cortex and of the genital glands, in dementia paralytica of the cortex and of some other organs, are present in the circulation and give rise to protective ferments which are demonstrated by Abderhalden's methods; whereas in the psychoses known as "functional" and "constitutional" (e.g., manic-depressive insanity, paranoia) no ferments are present. For the present the main interest attaching to these observations consists in the encouragement they afford us in our attempts to diagnose between the dementia præcox group with its practically hopeless prognosis on the one hand, and confusional states and mania and melancholia on the other. In this connexion it has to be noted that anti-proteolytic substances—substances which interfere with tryptic digestion—are also found in increased amount in the serum of cases of the "organic" as distinguished from the "functional" and "constitutional" psychoses.

---

[*] Lectures I. and II. were published in THE LANCET of Dec. 5th (p. 1287) and 12th (p. 1341), 1914, respectively.

TABLE XI.—*Differential Leucocyte Count in Percentages on 400 Consecutive Leucocytes.*

General paralytics in remission.	Date of admission.	Date of examination.	Leucocytes per c.mm. Average of 3 counts of 400 each	Polymorphs.	Small lymphocytes.	Large lymphocytes.	Eosinophiles.	Basinophiles.	Remarks.
W. T. M.	12/5/10	7/3/11	—	61·4	17·8	18·5	2·0	—	In remission, but not pronounced.
		5/7/11	9,000	51·75	32·25	15·50	0·50	0·25	Same state.
		17/7/11	17,400	86·5	11·0	2·5	—	—	Shortly after minor seizure with rise of temperature.
		28/6/13	11,400	76·50	17·50	5·00	0·00	1·00	In seizures.
		15/9/13	11,400	72·50	19·00	8·00	0·50	0·00	Seizures previous day.
		22/9/13	12,000	65·50	26·50	7·50	0·50	0·00	Confined to bed; faulty habits. Going steadily down. Died 11/1/14.
S. J. C. K.	2/1/11	23/3/11	15,484	55·0	23·75	17·00	4·0	0·25	Remission.
		25/5/11	—	41·7	20·25	30·50	5 75	1·75	,,
		3/2/12	8,400	74·75	16·25	8·00	1·50	—	1 week after seizure.
		24/10/12	13,900	70·75	10·75	15·50	2·50	0·50	In relapse; has been so some weeks; demented; restless.

		29/8/13	9,200	65·00	28·50	5·50	1·00	0·00	Restless and confused.
		10/9/13	11,000	61·00	25·00	9·00	2·00	1·00	Same. Died 29/10/13.
T. G.	25/2/11	12/11/12	11,000	64·02	21·75	13·50	0·75	—	Partial remission, but getting dirty (quiescent, rather).
		20/5/13	10,800	59·75	31·25	9·00	0·00	0·00	Remission; plays cards; up and about.
		22/7/13	12,200	49·50	39·50	9·00	1·00	1·00	Good remission as above; working.
		9/9/13	9,200	63·00	29·50	7·50	0·00	0·00	More demented; not working.
		6/11/13	14,500	60·00	30·00	10·00	0·00	0·00	Same.
		3/12/13	9,400	72·00	21·50	6·00	0·50	0·00	In seizures (minor).
		2/1/14	21,800	74·00	13·00	13·00	0·00	0·00	Temperature 102°. Cannot stand or speak; "suppressed fit" according to attendant.
		21/1/14	16,600	65·50	19·50	15·00	0·00	0·00	Up again; getting more demented; clean.
		29/1/14	15,400	69 00	16·50	14·50	0·00	0·00	Up again; not working.
		10/2/14	14,600	79·00	13·00	8·00	0·00	0·00	Temperature 99·2°. Confused; "suppressed fit."

They are increased—and more especially in exacerbations of or in pronounced cases of the malady—in epilepsy, dementia præcox, dementia paralytica, dementia senilis, but not in simple functional melancholia nor in paranoia. These are the conclusions of Pfeiffer and de Crinis[3] (1913), who have, I think, done the most extensive work in this direction. I give here tables of antitryptic tests which I have carried out. The technique I employed was that recommended by Pfeiffer and de Crinis, but the serum to be tested was used in a dilution of 1 : 40 and not 1 : 20, as in their cases, as I found that the sera of my patients prevented trypsin digestion too strongly in the latter dilution. Hammersten's casein (1 per cent.) and Merck's trypsin (0·1 per cent.) were used, freshly prepared each time. The titre of the trypsin was ascertained, the solution being placed against a fixed quantity of the casein solution in amounts increasing by 0·1 c.c., from 0·1 c.c. to 1·2 c.c. The tubes, after 30 minutes in the incubator, had three drops of an acetic-alcohol mixture added in each case. The first tube to remain clear—free from cloudiness—at the close of 30 seconds was taken as indicating the titre of trypsin. The inhibiting power of the serum from different cases was ascertained by adding a fixed quantity of the diluted serum to the trypsin-casein solution, in progressively increasing strengths of trypsin, as above indicated. The tubes were treated as above. The first clear tube in each series was noted, and the figure compared with the titre figure. If the first tube clear in the titre series were 0·7, in the control serum 1·3, and in a patient's serum 2·0; 1·3 less 0·7 = 0·6; 2·0 less 0·7 = 1·3. Multiplying these figures by 100, we get 60 and 130 respectively, representing the antitryptic units in the control and in the patient respectively. This explanation will serve to make the accompanying Tables (XII. and XIII.) comprehensible. It will be seen that the antitryptic unit is, with few exceptions, higher for the patients tested than for the control (a farm patient, chronic, quiet dement) on the same date. It is highest in cases of active dementia paralytica and senile dementia (S., Y., Bl., C), all near death (katabolism marked). One case (Sm.), recurrent confusional insanity, unit = 130, is anomalous. Cases of dementia paralytica in remission (St., W.) have a lower figure than the active cases (S., Y.).

Nothing is known as to the nature of these antitryptic substances; at present, at any rate, there is no sufficient evidence to show that they are connected with the *abbau produkte* upon which the Abderhalden test depends, or with products of incomplete protein-metabolism. The important point about this modern work in respect to ferments and antiferments in the serum, as far as it concerns the domain of psychiatry, is that it affords considerable reason for hoping that by its means we shall be enabled to distinguish between "functional" and "organic" disease, or that which is recoverable and that which is irrecoverable (in the present state of our knowledge). But this work does not throw light upon the ultimate problems of pathogenesis in the "organic" disorders. It is precisely in the instances in which ferments and antiferments are shown to exist that the products of degeneration of the nervous or noble element of the cerebral tissue are to be found by the histological methods of Alzheimer, together with amœboid glia-cells in abundance, which themselves undergo degeneration when their function of removing and transporting break-down products of the nervous tissue to the perivascular lymph-channels has been fulfilled. In these cases the glia-cells and lymph-channels

around the cerebral blood-vessels are to be seen loaded with the products of disintegration, which of course pass into the circulation. The nature of these breakdown products requires to be investigated by micro-chemical methods.

INFLUENCE OF INTERCURRENT DISEASE.

I would now ask your attention to the subject of the amelioration and cure of mental maladies through the agency of intercurrent disease, and of methods based upon this object-lesson of nature. Amongst the general diseases which are instrumental in this manner, typhoid fever, erysipelas, and ague are probably the most potent. Within the last year I have seen two cases respectively of stupor and of melancholia, in which scarlet fever was followed by amelioration, in one of them recovery taking place. Severe attacks of asylum dysentery also produce amelioration. But these diseases do not appertain to any particular class, such as that of the specific fevers; neither can it be said that the therapeutic effectiveness of a malady depends upon the degree of fever associated with it. This is in accord with experience obtained with methods, hereafter to be referred to, for the promotion of leucocytosis; the beneficial result is not necessarily associated with pyrexia. In what manner the cure of mental disorder by intercurrent bodily disease is effected, we are ignorant. It is idle to enter into explanations of a purely hypothetical kind, and the most I shall allow myself is to say that the suggestion put forward by Kauffmann, to which reference was made in the first lecture, to the effect that the improvement in question is due to quickening of oxidation and of removal of products of metabolism, is worth attention. In the meantime we have to take note of the fact that a hyperleucocytosis is frequently present in these intercurrent maladies. I have mentioned above certain diseases which have a particularly favourable effect upon recoverable insanity; others which often exercise a powerful influence for good are pneumonia and septic infections, especially extensive cellulitis. It is mainly in mania, melancholia, and confusional states, and in comparatively early cases, that one sees marked improvement and cure, but sometimes also in apparently hopeless cases of long duration. Stuporose states, such as nowadays would probably be termed "hebephrenia," are also benefited. I have never seen a case of the katatonic variety of dementia præcox improved in this way, nor one of insanity with epilepsy, nor of systematised delusional insanity, but as regards this last I have never had a case under observation in the very early stage. It is therefore the psychoses which lend themselves to the theory of a toxic origin which are benefited.

As regards dementia paralytica, all with experience have observed the remarkable remissions induced by intercurrent disease. This is usually of a local kind, taking the form of extensive cellulitis or septic abscess in consequence of the habits and predisposition of the patient. High fever of long duration is usual, and the illness is severe. On recovery the patient frequently has a pronounced remission, so that he can be discharged to the care of his friends, and remains comparatively well for a year or more. My experience in this regard has been with cases of the disease several months to a year and more old; and I should say, judging by the literature, that reliable records of cases in which a remission was induced by intercurrent illness quite early in the disease are very uncommon. It is especially these which would be of interest. Instances of remission of extraordinary duration are on record; thus, Jurmann,[4] a Russian observer, records cases which lasted from 4 to 12 years, following upon phlegmon of a limb, gangrene of the lung, typhoid fever, and extensive burns. Such instances serve to show that the action of the causative agent (? spirochæta) or agents can be checked.

Attempts have been and are being made to benefit by the example furnished of the amelioration and cure of mental disorders by the agency of intercurrent bodily disease. In the absence of knowledge of the *modus operandi* in these cases, our efforts are at present limited to the application of methods calculated to produce leucocytosis or fever. Such indications as we possess point, I think, to the propriety of the former rather than the latter. Physicians up to some 30 years ago would appear to have favoured the hypothesis that intercurrent disease acted through the medium of the fever which accompanied it, or possibly of the "counter-irritation," in the case of localised inflammation, such as cellulitis. Up to 25 years ago blisters were applied over the mastoid processes, in cases of stupor especially, but the earlier practice of placing a seton in the nape of the neck or of blistering the scalp had been abandoned. These methods were sometimes based upon the hypothesis that peripheral stimulation of the cranial and cervical nerves might favourably influence the cerebral cortex, more commonly upon the theory that a "reaction"—by which an alteration of cerebral metabolism was probably meant—could be induced. Next in order came the attempts to promote a sterile abscess in such parts as the loin or buttock by means of turpentine. These have not found favour, although Bruce[5] and others have recorded cases of mania in which the attack was arrested and recovery hastened, mental improvement being associated with great proportional increase in the neutrophile cell count. The difficulty and risk associated with the nursing of an irresponsible and restless patient, of faulty habits, under the circumstances, can be appreciated.

TREATMENT BY NUCLEINATE OF SODA.

Since about 1909 the drugs used, chiefly hypodermically, have been such as promote leucocytosis; thus, cinnamate of soda, nucleinic acid, and nucleinate of soda. The last-named is now most in vogue, and has been mainly employed and advocated by Fischer, of Prague, and Donath, of Budapest, more especially for the purpose of inducing remissions in dementia paralytica, but of late also for promoting recovery in dementia præcox. Fischer[6] reported in 1909 upon 22 cases of dementia paralytica, in which, by the hypodermic injection of sodium nucleinate, a leucocytosis of 16,000 to 25,000 was produced, lasting three days. In 4 long-lasting remission was obtained, 4 died, and the rest had remained stationary since 1908 (date unmentioned). Of 22 untreated cases none had remissions and 8 died. In a second series the dosage was ½ to 3 grammes in aqueous solution every three to five days. Of 10 patients so treated, 5 showed well-marked remission, which later passed off. Of 10 controls, only 1 showed a remission, due to an intercurrent septic process. Donath[7] has had a large experience in this treatment, and is its main advocate. He first recommended a 2·5 per cent. to 3 per cent. aqueous solution of sodium nucleinate, and injected 50–100 c.c., and gave eight injections at intervals of five to seven days. The temperature only rose 2 or 3 degrees after injection and fell to normal in about three days. A leucocytosis of 21,000 per c.mm. was produced on the average, but as much as 61,000 was reached. His first series comprised 21 cases of dementia paralytica. Ten were improved to the extent that they were able to work and earn money, and 5 so that they returned home; 6 were unchanged. The longest duration of improvement was three years. In a second series 3 out of 15 were improved to the extent that they could work as before; 6 were merely improved, the remaining 6 not improved. Hüssels[8] used doses of from 1 to 2·5 grammes in aqueous solution, as much as 100 c.c. being injected at a time and every four days, seven injections in all. Pyrexia reached 40·3° C., but leucocytal increase amounted to from 60 per cent. to 100 per cent., and leucocytosis lasted rather longer than pyrexia. Of 5 cases of dementia paralytica so treated, 4 were advanced in the disease; the fifth was not and showed evident improvement. Lomer,[9] with doses of 4 grammes in 100 c.c. of water, had no good efforts. Jurmann[10] obtained improvement in 7 out of 17 cases of dementia paralytica, as indicated by evidence adduced. Itten,[11] who treated 9 cases of dementia præcox without any permanent benefit, employed the nucleinate in quite insufficient doses, so that his results must be discounted. The necessity for intensive treatment was dwelt upon by Donath in his communication upon this method at the last International Congress of Medicine. Lépine[12] had no success in 13 cases of dementia præcox, but claims to have obtained 8 cures and 2 improvements in 13 cases of manic-depressive insanity and cure in 7 out of 8 cases of "confusional" insanity, notable improvement in the one. Lundvall[13] employed up to 3·8 grammes sodium nucleinate as a single dose, adding arsenic and sodium cinnamate to increase the leucocytagogue effect. Hyperthermia subsided in 24 hours, whilst leucocytosis lasted a day or two longer. Of 18 cases of dementia præcox, 4 recovered and 9 were considerably improved. Donath, in his communication referred to, states that he now employs a 10 per cent. of sodium nucleinate dissolved in 1 per cent. of sodium chloride. The dose of the drug ranges from 0·5 to 5·0 grammes, so that the largest bulk of fluid injected would be 50 c.c. Injections take place every 4 or 5 days, and 6 to 12 are given. Of 14 cases of dementia præcox thus treated, 3 were regarded as cured—they took up their work again, that is to say; 5 were improved. The cured and improved cases—taken together—reported by Donath and Lundvall respectively amounted to 57 per cent. and 72 per cent. These are remarkable figures compared with the ordinary ones, gathered from cases which have received no particular treatment. Recovery may be said to occur in from 13 per cent. to 20 per cent. of the katatonic group, which is the least unfavourable one. The latest figures are, I believe, those of H. Schmidt,[14] published in 1912, based upon the histories of 450 cases of dementia præcox discharged between 1901 and 1910. He found recovery in 16·2 per cent., in 15·5 per cent. recovery with defect. If the results of Donath and Lundvall are approached by other workers there will certainly be ground for the dictum of the former, that henceforth the passive attitude adopted towards cases of dementia præcox in respect of treatment is unjustifiable. In 1913 Moretti,[15] from his favourable experience with sodium nucleinate, thought the method justified in early cases. Cases such as those reported by Lépine and by Brown and Ross,[16] in which psychoses with indications of a toxic origin, such as mania-melancholia, acute confusional, and acute delirious conditions, have been cut short by injections of nucleinic acid, in some cases preceded by colloidal silver (and in all cases there was pronounced leucocytosis), show that the dogma that no measures can interrupt or modify the course of psychoses of this type is not correct.

Changes induced by Sodium Nucleinate.—Colloidal Metals.

In the absence of statements as to the qualitative cell count in cases which have received injections of sodium nucleinate it may be as well to mention that in the cases which I have injected, with from 50 c.c. to 100 c.c. of a 2 per cent. solution, the neutrophile cells showed a considerable proportional rise in number as a result of the injections. For the rest, there was always leucocytosis and increased pulse-rate; this was a more marked feature than rise in temperature or in the respiration rate. The changes noted passed off in a few days. I have found, in common with the observers quoted, that the effect produced on the temperature and respiration of the patient is negligible; there may be a rise of a degree or two in the former, but any such effect is very transient. Whereas the pulse-rate is notably increased, and this change, together with the leucocytosis, lasts a few days longer than any change in respect of temperature and pulse. The changes induced can be maintained for a considerable period by regular treatment, but the influence of the drug passes away in time. The favourable results which have been reported in disorders with a toxic origin as a result of the employment of colloidal metals (collargol, electrargol, leptynol—this last is the colloidal form of palladium) point to the desirability of using them in the same kinds of mental disorder as are favourably influenced by sodium nucleinate. I cannot here enter into the statements which have been made concerning the manner in which these colloidal preparations act (by promoting oxidation, especially); no sufficient evidence has been produced for them. But there is definite evidence that these substances produce a leucocytosis with increase in the neutrophile percentage, and a considerable increase in the opsonic power of the serum.

THE EFFECTS OF TUBERCULIN AND OTHER TREATMENT.

The attempts to promote the general powers of resistance in dementia paralytica, and to induce and prolong remissions by means of the injection of tuberculin, appear to have originated with the Viennese school, and have been mainly employed and advocated by Wagner von Jauregg and Pilcz. Although employed by the Viennese teachers and their pupils for more than 10 years, it cannot be said that any noteworthy publications have appeared from other sources; the method has not, in fact, been tested to any extent elsewhere. The dose of tuberculin commences at 0·01 mg., and is increased every second day by 0·02 mg., when reaction is weak or absent, by 0·05 mg. The maximum dose in most instances is 0·5 mg., but it has been as much as 1·0 mg. A febrile reaction of more than 39° C. is an indication that treatment should cease. No fever should be present on the day of injection. Both Wagner and Pilcz have drawn attention to the desirability of selecting early cases for treatment. The duration of the disease in patients usually received into public institutions renders them unsuitable subjects. The chief publications of Wagner and Pilcz[17] known to me are mentioned in the bibliography; here I propose merely to refer to three groups of statistics, two of which are from the latter observer. The first deals with 66 cases of dementia paralytica treated as described, and 66 untreated ones. Of the former 20 and of the latter 39 died within the first year. At the close of four years 8 treated and 5 untreated were alive, the former in better mental and physical condition. In 1911 Pilcz published results in 86 cases, a considerable number of which were in quite an early stage of the disease; in 52 (60·32 per cent.) there was a favourable influence, of which 20 (23·2 per cent.) showed merely a quiescent condition; 9 (10·44 per cent.) marked remission lasting one to two years or more; and 23 (26·8 per cent.) got well to the extent that they resumed work (of whom 10 still remained at work two years later). Meyer,[18] in a publication appearing in 1912, gives the results of the Wagner-Pilcz treatment at the large Viennese asylum "am Steinhof." Of 112 cases of general paralysis 51 (45·5 per cent.) were uninfluenced, 22 (19·6 per cent.) showed slackening in the rate of progress of the disease, 28 (25 per cent.) marked remission, and 11 (9·9 per cent.) took up work again. From the combined statistics of Pilcz and Meyer it appears that from 35 per cent. to 36 per cent. of the cases treated passed into a remission of a marked kind. Statistics on the point are unknown to me, but I believe that this is a higher degree of frequency than what is observed in the untreated disease. Those with experience claim that improvements and remissions occur oftener and last longer in cases treated with tuberculin than in those who receive no treatment. The method is stated to be without danger in the absence of tuberculosis. According to Gulland and Goodall, in their work, "The Blood," injections of tuberculin are followed by an increased leucocyte count, there being an increase of neutrophiles and frequently also of lymphocytes. In certain cases under my care a relative lymphocytosis resulted from such injections, and I therefore suggested to Dr. D. L. Jackson, then assistant physician at Cardiff Mental Hospital, that he should observe the comparative white cell counts in cases of dementia paralytica who were receiving tuberculin. These were six in number, four receiving T.R. and two T.B.E. The dosage began with 0·0001 mg. in each case and was gradually increased to 0·01 mg. No changes occurred in the qualitative leucocytal counts until doses ranging from 0·0002 mg. to 0·001 mg. were employed; between these limits a lymphocytosis began to appear; the percentage of lymphocytes rose to as much as 50 in some of the cases. With the higher doses no more marked changes were found than when 0·001 mg. was given.

These results lead one to inquire whether the beneficial effect recorded as following upon the use of tuberculin in cases of dementia paralytica may be associated with the production of lymphocytosis, which would be an explanation based upon the observations recorded at the beginning of this lecture, with reference to the qualitative leucocytal count in states of remission and quiescence. This explanation would not account for improvement brought about by the use of sodium nucleinate. No relationship seems to exist between febrile reaction and the favourable results obtained with tuberculin; as with sodium nucleinate, so in this case, any increase of temperature produced is very slight.

Recently mercury or salvarsan has been used in combination with sodium nucleinate or tuberculin. Whilst a higher degree of leucocytosis is obtainable in this way there is the possibility that the resulting benefit is due to the direct action of these drugs rather than to leucocytal action, the cases treated being in reality not cases of dementia paralytica but of cerebral lues in the usual sense. But Pilcz,[19] at the Congress of Neurology and Psychiatry held at Ghent last year, stated that remissions of much more marked and prolonged kind are obtainable in undoubted general paralysis by this means than occur spontaneously, and that they occur in the most unfavourable type of case, and occur repeatedly on repeated injection. Other methods, which are also methods whereby leucocytosis is promoted, such as the inoculation of dead cultures of staphylococcus and streptococcus, are now being tried in dementia paralytica. Marked remissions are noted after infections in which staphylococci more especially are concerned. Wagner[20] has recently obtained striking remissions in seven cases of this disease, of the maniacal type, by the use of polyvalent staphylococcal vaccine. Here, again, the temperature was but slightly affected, whereas the increase in the pulse-rate was marked.

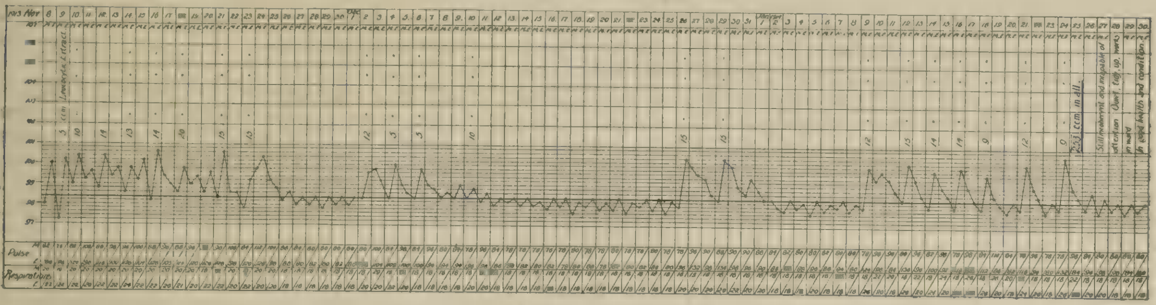
LEUCOCYTE EXTRACT.

In 1908 Hiss[21] published observations upon the curative influence of extracts of leucocytes upon infections in animals. These observations were followed by others, developing out of them, by the same and other workers. In the bibliography I give the references to this work, and must content myself with a brief account of the principles upon which it was based, the application of these in practice, and the results. Hiss[21] discusses the hypotheses and facts of immunity, and advances the reasons which support the belief that leucocytes play a dominant part in the protection of the animal economy.

Proceeding upon the hypothesis that "substances—digestive, poison-neutralising, complementary—might possibly be liberated from leucocytes by methods of extraction and introduced in this free condition into infected animals or man," he experimented upon animals (rabbits) in which certain prevalent infections had been produced by inoculation with organisms (staphylo- and streptococci, pneumococci, meningococci (typhoid)), so that they suffered from severe septicæmia or toxæmia. These received extract of leucocytes prepared from normal or immunised rabbits, with the result that they survived infections rapidly fatal to control animals; the beneficial effect of this treatment was apparent by such indications as fall in temperature and gain in weight. The exact action of the extracted substance is a matter of conjecture. Zinsser[22] has shown that the extract contains bactericidal substances in insignificant amount compared to the serum, and contains no complement. Hiss and Zinsser, in a subsequent communication in the same periodical, give reasons for ascribing the favourable influence of the procedure adopted to a "faculty of neutralisation towards toxic-bacterial products possessed by the extract." This explanation is borne out by observations by them upon the treatment as applied to infections in man. The beneficial results observed in epidemic meningitis—

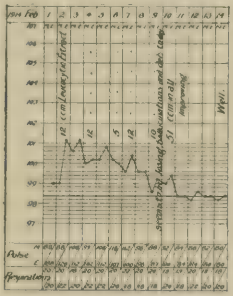
especially the promptitude of the reduction of such symptoms as vomiting, delirium, stupor, and reduction of temperature—are most reasonably explained upon the theory of neutralisation of toxin. The like holds good for the favourable results obtained in lobar pneumonia. Hiss and Zinsser, in the same periodical, report upon these. Floyd and Lucas[23] follow in a later number with a larger series of cases of this disease. They approximately standardised the extract, so that about 20,000,000 leucocytes were given in 10 c.c. of water. About 10 c.c. injected subcutaneously twice daily was their ordinary dose, but in severe cases as much as 20 c.c. were given three or four times in the 24 hours. They found that no harm was done by the extract, whilst in a number of cases the disease was apparently shortened. Noticeable improvement in the symptoms and in the comfort of the patient was seen. Toxæmia was notably lessened. Up to the date of these observations there was not sufficient material upon which to study case-mortality in cases treated with the extract and in cases untreated. The latest paper on this subject which has come to my notice is one by Hiss,[24] published in 1913, in which he confirms the utility of leucocytic extract in the control of infectious disease, whether general or local, and given reasons for the view that the beneficial results obtained are due, not to a bactericidal or phagocytic action of the leucocytes employed, but rather to a poison-neutralising or poison-prohibiting action.

FIG. 10.



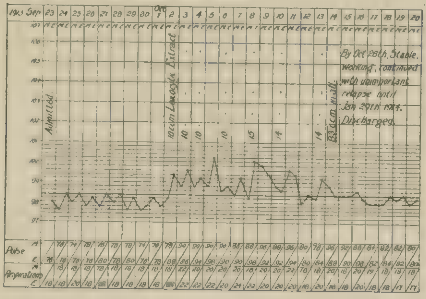
Acute mania; fairly good condition. E. B., aged 22, admitted Nov. 6th, 1913. (The lettering on the chart shows the administration of c.c. leucocyte extract, 253 c.c. in all, being reached on Jan. 25th, 1914. By Jan. 27th, though still incoherent and incapable of attention, he was quiet and working in the ward. On Jan. 30th he was in good health and condition.) (The figures and lettering are clear under a hand lens.)

FIG. 11.



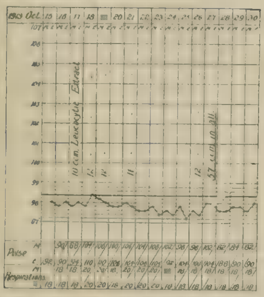
Acute confusional case; marked hallucinations. R. B., aged 32, admitted Jan. 28th, 1914.

FIG. 13.



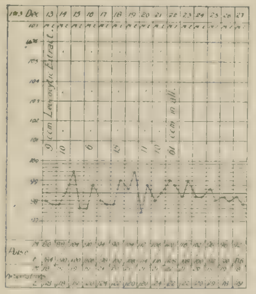
Acute delusions; agitation; physical reduction marked. E. W., aged 22, admitted Sept. 23rd, 1913.

FIG. 12.



Melancholia. A. S., aged 26, admitted Sept. 12th, 1913. (The patient's physical reduction on admission was marked. The chart ends on Oct. 30th. By Nov. 10th he was working and was discharged on Nov. 27th, 1913.)

FIG. 14.



Acute confusion. S. P., aged 26, admitted Dec. 9th, 1913. (The patient's physical reduction on admission was marked. By January, 1914. he was working, and at the close of the month was awaiting discharge.)

Employment of Leucocyte Extract in Mental Cases.

The perusal of the beneficial effects produced in acute infective diseases by the early administration of leucocytic extract—and I have to thank my colleague, Dr. Schölberg, for bringing this literature to my notice—suggested the application of this treatment in cases of acute and recent insanity, similar to those in which sodium nucleinate and like drugs have been employed. In this connexion I would allude to the observations recorded in the second lecture, which showed that for some unknown reason a higher opsonic index was found in respect of two organisms (intestinal anaërobes) when the patient's leucocytes were replaced by those of a healthy control. This observation does not demonstrate more than a greater capacity for ingestion of organisms on the part of the healthy control's leucocytes. But we are not restricted to the dogma that the rôle of the leucocyte is entirely a passive one, and the results obtained in toxic conditions by the American observers whom I have cited are scarcely to be explained on this view. It appears to me very desirable that a thorough trial should be given to the method in such descriptions of mental disorder as acute mania and melancholia, acute confusional states with hallucinations, stuporose conditions, psychoses of exhaustion, and as early as possible in these conditions.

For the past two years I have given considerable attention to the preparation of leucocytic extract upon the basis of the American work recorded, and of late I have been able to obtain it in sufficient quantities for use, and have employed, and am employing, it in cases of the kind mentioned. For the purpose of producing an exudation of leucocytes in the pleural cavity of the rabbit aleuronate was employed, as recommended by Floyd and Lucas. The animal should be in good condition and weigh from 1600 to 2000 grammes. A 5 per cent. suspension of aleuronate in cold starch was added to double-strength neutral broth whilst boiling. Sufficient of the boiling broth was rubbed up with the starch suspension to make a suitable emulsion, and the mixture was then put into the boiling broth; the latter was then sterilised. The aleuronate-broth mixture appeared to lose its potency at the end of two to three months, and a fresh supply was made. Floyd and Lucas were able to obtain an exudate in 24 hours by injection of this mixture to the amount of 10 c.c. into each pleural cavity. This seems an enormous amount. Schölberg and I, in our earlier experiments, used the mixture as described, but in less amount, about 2 c.c. being injected into each cavity. We found that little or no exudate was produced. By mixing pure turpentine with the aleuronate mixture in the proportion of 1 to 4, and injecting about 1·2 c.c. into each pleural cavity, we obtained an exudate with a considerable degree of regularity, the best results being achieved when the rabbit was killed in about 48 hours. The nature of the exudate varied in different animals, as also its amount. Sometimes there was a serous effusion comparatively deficient in leucocytes, sometimes a very turbid exudate, quickly becoming semi-gelatinous in a tube; and the amounts obtained from individual rabbits varied from 10 to 60 or more c.c.

The technique of collection which I employ is as follows. The animal is killed by chloroform, stretched and tied supine, its thorax and the abdomen adjoining shaved, the flesh thoroughly seared. The pleural cavity on each side is then cut open with sterile scissors, and the exudate drawn up in sterile 10 c.c. pipettes and placed in sterile 10 c.c. centrifugal tubes, 5 c.c. in each tube; to each tube sterile citrate is added, allowing sufficient room for fitting a sterile rubber cork. Each tube is well shaken, and the tubes are then centrifugalised for half an hour. The supernatant fluid is then pipetted off, and sterile salt solution (0·85 per cent.) added to the deposit of corpuscles. The tubes are well shaken and placed in the incubator at 37° C. for 24 hours. The contents are then transferred to sterile Pasteur flasks, not more than 10 c.c. to each flask, to minimise the loss in case of contamination during the proceedings detailed, and to each flask 0·5 to 1 c.c. of a 10 per cent. solution of phenol is added. The flasks are then kept in the ice chest. By inoculating a broth tube from each Pasteur flask and incubating for at least 24 hours, it was ascertained that the contents of the flask were sterile before use. I have not hitherto found time to work out an approximate standardisation of the exudate. It will be seen from the accompanying charts (Figs. 10 to 14) (specimens of those exhibited at the lecture) that the daily doses given have been of moderate amount; much larger doses were given by Floyd and Lucas in pneumonia. These being the first cases I have dealt with I restricted the dose, but should not do so in future cases. The injections were made subcutaneously between the scapulæ. Out of some 80 injections, averaging about 8 c.c. of extract to each, not one was attended with any untoward result. The patients were, of course, kept in bed the whole time. The charts show that the injections produced a marked acceleration of pulse-rate, very slight acceleration of the respiratory rate, and usually a slight rise in temperature. Control injections with 10–15 c.c. of physiological salt solution produced no effect in any of these directions. The charts deal with but few patients, and it would be premature to record any therapeutic results; but the method is one to be persevered with. The following table (Table XIV.) shows that an absolute and relative polynucleosis is produced by the injection of leucocytic extract. [Only one case—B. W.—is given here for reasons of space.]

TABLE XIV.—*Effect upon the White Blood Cell Count of Injection of Leucocytic Extract.*

The total of each count is the average of the figures per c.mm. deduced from reckoning three sets of 400 squares each. The percentage of polymorphs is based upon 400 cells for each count.

	Leucocytes per c.mm.		Percentage of polymorphs.

H.	15,266 (average of 3 counts).	12,066 (average of 3 counts).	61·00 (average of 3 counts).	64·50 (average of 3 counts).

THE PRECIPITIN TEST IN THE PSYCHOSES.

The discovery of precipitin is based upon researches into the problems of immunity, and is due primarily to the work of R. Kraus. It has been shown that the serum of an animal which has been repeatedly injected with serum from another animal of a different kind gives a precipitate when brought into contact with the serum used for injection or with that of an allied animal in certain proportions. Thus, the serum of rabbits which have been so injected with human blood-serum gives a precipitate with such serum, and with the serum of apes, but not with other serum. Similar "related reactions" exist in other instances; thus "antiserum" from a fowl gives precipitate with pigeon's serum; from a horse with donkey's or tapir's; from a fox with dog's serum. As you are aware, this reaction has been extensively employed for forensic purposes, especially by Uhlenhuth. The precipitin reaction does not seem to have been widely tested in respect of its efficiency as a diagnostic agent in disease. Uhlenhuth and Weidanz in their work upon the formation of precipitin and the precipitin test refer to an experiment by Kullmann, who immunised rabbits with extract of carcinoma, and thus obtained a precipitating serum, which, however, gave no specific reaction with the serum of patients affected by carcinoma, a precipitate being likewise obtained by adding it to the serum of cases of nephritis or of healthy persons. As far as carcinoma is concerned, it has been shown by Romkes, whom the above-mentioned authors cite, that when all normally precipitable substances have been thrown down from the serum of the cancer patient by the addition of serum from a rabbit previously treated with normal human serum, no further precipitate is obtainable by adding antiserum from a rabbit injected with cancer emulsion. In other words, the precipitate formed with the carcinomatous serum on addition of its antiserum is not specific but is the same in nature and quantity as that formed with the same serum on addition of normal rabbit antiserum. The question as to whether specific precipitins can be produced by inoculating rabbits with serum from different kinds of insanity has received no attention, as far as I am aware, except from Geissler.[25] He states that the rabbit antiserum of cases of the katatonic variety of dementia præcox gave a precipitate in greater amount and in higher dilutions with the serum of katatonic cases than with that of a healthy sane control. The same applied to cases of the hebephrenic variety, and in both instances to all cases and not merely to individual ones. The observation did not hold good with the paranoidal form of the disease. The antisera in question gave no precipitate with the sera of general paralytics, epileptics, senile dements, neurasthenics, and others. If Geissler's observation is correct, a specific precipitin reaction occurs in the two chief varieties of dementia præcox. Ceni[26] found that the precipitating properties of epileptic serum did not differ from those of normal serum. Besta,[27] experimenting with pellagra serum, found no specificity of reaction.

In the absence of anything approaching adequate information, it seemed desirable to experiment with the blood of certain of the insane with a view to determining whether specific precipitins could be produced by inoculation of rabbits, and for this purpose Schölberg and I selected cases of dementia paralytica and dementia præcox; the former presenting well-marked symptoms of the second stage, the latter in an active stage of the disease. Blood was received from an arm vein through a sterile cannula into a sterile bottle, and the serum allowed to separate. Rabbits were inoculated intravenously, in accordance with the practice recommended by Uhlenhuth and Weidanz, at intervals of seven days with from 2·5 to 3·0 c.c. of the serum. Seven days after the third injection, and before each subsequent injection, about 3·0 c.c. of blood was removed from the dorsal vein of the ear, centrifugalised, and 0·1 c.c. of the serum added to 1 c.c. of a dilution of 1 in 1000 (salt solution) of the freshly obtained serum of the patient whose blood was to be tested. The antiserum was thus tested on the seventh day after each injection—that is, about the time at which, according to Uhlenhuth and Beumer, the production of precipitin in the rabbit's blood is most active. We found that when a precipitate was about to be formed the clear fluid of the tube concerned showed a characteristic cloudiness within a quarter of an hour, but flocculi took longer to appear; and it was from one to three and a half hours before the actual precipitate was apparent. The animal furnishing the precipitin was immediately killed under chloroform, the blood allowed to collect and clot in a sterile bottle, the serum filtered through a porcelain filter and received direct into ampoules, which were sealed as filled. This filtration and collection was kindly carried out by Dr. Stanford, research chemist, Cardiff Mental Hospital. Our results may be tabulated in Table XV.

Remarks.—No. 3.—0·2 c.c. antiserum. Nos. 3 to 8.—Equal also results in all cases from No. 3 to No. 8 inclusive with antiserum obtained from a healthy person. Nos. 59, 60, and 61.—C.S.F. used instead of serum in these three. No. 102.—Remission.

The amount of precipitate, estimated by the eye, recorded as "trace," "+," "++," "+++."

C.S.F. = Cerebro-spinal fluid.

formed—10·6 per cent., or in 10 out of 94 instances. This illustrates the difficulty one meets with in the attempt to obtain information about precipitins; their production is most tedious and capricious, and not subject to control; dependent, in fact, upon individual qualities of the animals employed, of which one knows nothing. Fully grown rabbits, well nourished, weighing from 1800 to 2000 grammes, should be employed. It is seen that a precipitin was mostly obtained after injection of from 8 to 12·5 c.c. of serum, and that when the latter amount is exceeded the prospect of obtaining precipitin is small; in fact, it is not worth while to continue with the injections when no result is obtained with, say, 15 c.c. The loss of weight shown in individual instances was very considerable in the majority of the rabbits, and of 89 in which the weight was taken weekly during the inoculations, 73, or 82 per cent., lost weight. A table omitted for reasons of space shows the losses and gains in weight in those animals in which a precipitin resulted and in those in which it did not. Whereas only 1 out of 10 of the former class (10 per cent.) showed a gain in weight, 15 out of 79 of the latter (19 per cent.) showed such. I now produce portions from a table showing the results obtained by the addition of rabbits' antisera to the diluted sera of various kinds of insanity. (Table XVI.)

The points brought out in the complete table are these: seven antisera, from rabbits inoculated with serum from cases of dementia paralytica and dementia præcox, were employed against the sera of 173 patients in dilutions varying from 1 : 100 to 1 : 20,000. These patients illustrated many kinds of insanity—two exceptional cases (Nos. 7 and 8) were those of sane persons with florid syphilis, for trial with antiserum from a general paralytic. Each antiserum was put against the serum of the patient by the injection of which it resulted, also against that of patients with the same disease, and against sera of patients with other kinds of insanity. The results were estimated by naked-eye observation. (Uhlenhuth's special tubes were used throughout.) From these it is to be gathered that a given antiserum produces the same amount of precipitate, whether it be put against the actual serum by which it was produced, the serum of patients suffering from the same disease, or the serum of patients suffering from other kinds of insanity. And this obtains for the various dilutions employed. In cases Nos. 3 to 8 inclusive equal results were obtained (in the different conditions mentioned) with antiserum from a general paralytic and from a healthy person. In ten cases antiserum from a general paralytic was put against cerebro-spinal fluid from general paralytics, an imbecile, and a case of delusional insanity, in a dilution of 1 : 500. Either no precipitate or a mere trace resulted and without distinction as regards amount. With the pure cerebro-spinal fluid abundant precipitate resulted, but again without distinction. Evidently the reacting body is much less in amount in this fluid than in the serum.

Another way in which the question can be decided, as to whether additional or specific substances (precipitins) are produced in rabbit's serum by the injection of the serum of persons suffering from disease, over and above the normally resulting precipitin, is as follows: (*a*) the serum of the diseased person is first saturated with "normal" antiserum (i.e., serum from a rabbit inoculated from a healthy person); (*b*) the rabbit's antiserum which has been produced by inoculation from such diseased person is in like manner saturated with "normal" serum (i.e., serum from a healthy person), the precipitates which result are filtered off; and (*c*) the filtrates are brought together. This appears to be theoretically sound, but in practice I found in respect to (*b*) as follows (Table XVII.):—

TABLE XVII.

Normal person's serum.	Against rabbit antiserum "W" from a general paralytic.	Result.
Pure. 0·1 c.c.	$\frac{1\ :\ 500}{1\cdot5\text{ c.c.}}$	No precipitate; slight opalescence.
,,	Against rabbit antiserum from a normal person. (As control) $\frac{1\ :\ 500}{1\cdot5\text{ c.c.}}$	,,

The experiment was repeated, using 0·2 c.c. of the normal person's serum and 2 c.c. of the antiserum of the two rabbits; the result was the same. So that I was unable to proceed on the theoretical lines mentioned, but had to content myself with carrying out (*a*) of the above, filtering and adding the "psychosis antiserum" without prior treatment, with the results which are shown in Table XVIII.

TABLE XVIII.—*Added to 3 c.c. of Dilution 1 : 1000 of Serum.*

l. = Less. sl. = Slight. v.f. = Very faint.

The inferences to be drawn from the results shown in Tables XVI. and XVIII. are that specific precipitins are not obtained by the inoculation of rabbits with the serum of insane persons; that all precipitable substance in such serum is brought down by the precipitin present in "normal" rabbit antiserum, so that no further result is obtained when antiserum from a case of insanity is subsequently added. These being the results I obtained, it remains for me to mention that Geissler, in cases of the hebephrenic and katatonic varieties of dementia præcox, obtained, by the filtration method alluded to, a precipitate over and above the normal one, and which, therefore, was specific; at least, so I understand his account. This was in 1910. Geissler's results have not been confirmed that I am aware of, and it is highly probable his work has not been repeated, having regard to the difficulties in the way of such work.

DEVIATION OF COMPLEMENT EXPERIMENTS.

We determined in the next place to experiment with a view to ascertaining whether, by the method of complement deviation, any specificity of reaction between a rabbit antiserum and the serum of the case of insanity by which it was produced, and allied sera, could be found. Such a test is much more delicate than a precipitin reaction. For the purpose of this test the rabbit antiserum was, for convenience, regarded as the "antigen," the patient's serum as the "amboceptor." Guinea-pig's complement was used, and the usual hæmolytic serum, sensitised to sheep's corpuscles. The titre of the "antigen," complement, and hæmolytic serum was ascertained, as for the Wassermann test. As a control "antigen" the serum of a normal uninjected rabbit was employed. A further control was instituted, as in the Wassermann test, by omitting "antigen" in one or more tubes in the case of each of the sera tested. The complement was of course destroyed in the case of all the sera, whether of rabbit or of patient. After a considerable number of preliminary experiments three sets of reliable results (with three antisera) were obtained, and these I show in Table XIX.

The extraordinary delicacy of this test is apparent, especially from the last case in the table, which shows complement deviation in two instances with dilutions of 1:100 million. There is, however, no specific complement deviation with the highest dilutions of the patient's serum, so that the test will not serve for purposes of differentiation. But here again the results recorded by Geissler are out of accord with those I record, inasmuch as he obtained deviation of complement of a specific kind in the case of serum of the hebephrenic and katatonic varieties of dementia præcox.

SURGICAL AID SOCIETY.—The Lord Mayor of London presided last week over the annual general meeting of supporters of the Surgical Aid Society at the Mansion House. He stated that the society during its 50 years' work had distributed 856,696 appliances. A vote of thanks was passed to Sir Frederick Treves, who has resigned the post of honorary consulting surgeon.

A METHOD OF TREATING THE SAC IN THE RADICAL CURE OF FEMORAL HERNIA.

BY J. PHILIP BUCKLEY, M.A., B.C. CANTAB.,
M.S. LOND., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.

THE following method of dealing with the sac of a femoral hernia is so simple, in my opinion so efficient, and so completely obliterates the sac, the obliteration of which is the most essential step in any operation aiming at a radical cure, that I feel I need offer no excuse for describing the operation in detail, especially as, so far as my reading of surgical literature goes, I have not seen this method described. During the last three years I have performed this operation some 30 times. I have no statistics to offer, but the fact that no patient has returned to me with a recurrence is significant. In cases which I have had an opportunity of examining some time after the operation I have been very satisfied with the apparent efficiency of the cure.

FIG. 1.

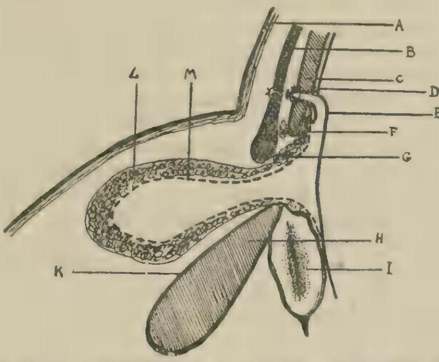

Diagram showing sagittal section through crural canal and femoral hernial sac, and demonstrating the sac before and after invagination. A, Skin. B, Aponeurosis of external oblique. C, Internal oblique and transversalis conjoined. D, Parietal peritoneum. E, Invaginated sac ligatured and fixed. F, Spermatic cord. G, Poupart's ligament. H, Pectineus muscle. I, Horizontal ramus of pubis just external to symphysis. K, Pectineal fascia. L, Fatty covering of peritoneal sac. M, Sac *in situ* before invagination.

My method of procedure is as follows:—

1. The skin incision is made, commencing about 1½ inches above the inner end of Poupart's ligament and vertically above the crural canal, extending down to 1½ inches below the external opening of the canal and having a slight convexity outwards. I prefer the external convexity in that it gives more room and removes the suture line further from the genital organs than does the ordinary straight vertical incision.

2. The hernial sac, covered by its layer of properitoneal fat, is exposed and thoroughly separated as far as the opening of the crural canal into the thigh.

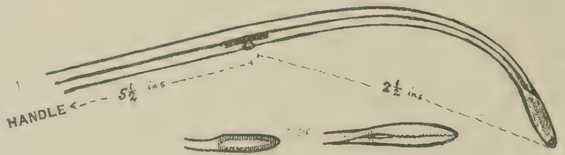
3. The upper end of the wound is held open by retractors, the surface of the aponeurosis of the external oblique muscle cleaned and an incision made in it parallel to its fibres about 2 inches long and ½ inch above the external ring of the inguinal canal. The conjoined tendon is thereby exposed.

4. The properitoneal fat, covering the true sac of the hernia, is now removed as completely as possible.

5. An opening is made with scissors at the apex of the sac, the contents, if any, are reduced, and

any adhesions separated. The edges of the sac are held apart by Spencer Wells forceps, and the forefinger is passed through the crural canal into the abdominal cavity. If the crural canal is too small to allow the passage of the forefinger then the little finger is used. I have met with cases where before the little finger could be passed I have had to insert the blades of a Spencer Wells forceps and dilate the neck of the sac by gently separating the blades. The finger when passed is flexed forwards so that the tip presses against the conjoined tendon. A pair of closed curved "catch" forceps (see Fig. 2) is passed along the flexor surface of the inserted finger until the tip of the forceps is against the conjoined tendon; the tip of the forceps is pushed through the conjoined tendon, and appears at the upper end of the skin incision. The opposed surfaces of the blades of the forceps are grooved, the better to hold a closed pair of Kocher's hernia forceps, the tips of whose blades are now inserted between the blades of the curved forceps. The latter are withdrawn with the Kocher forceps in their grip, so that the blades of the latter forceps appear at the opening at the apex of the hernial sac. The passage of the finger through the crural canal is important at this stage, as thereby the danger of injuring or nipping intestine or omentum by the blades of the forceps is avoided.

FIG. 2.



6. The edges of the sac are then caught between the blades of the Kocher forceps and the sac is pulled inside out, appearing through the conjoined tendon. This manœuvre is carried out gently but firmly, and the peritoneal lining of the crural canal is stripped completely away from the canal and invaginated together with the sac of the hernia.

7. The sac is transfixed with a full-curved needle, threaded with catgut, close to the conjoined tendon, ligatured, and then cut away. One end of the catgut is again threaded and the needle passed through the conjoined tendon on one side of the stump, through the stump itself and through the tendon on the other side of the stump, and the two ends tied, the stump thereby being fixed to the conjoined tendon, and retraction being prevented.

8. The slit in the aponeurosis of the external oblique muscle is closed with a continuous catgut suture; the pectineus muscle and fascia are brought into apposition with Poupart's ligament by a stout catgut suture; the skin incision is closed with silkworm gut, and a gauze dressing and firm spica bandage applied.

In practising this operation it is at once obvious that it is necessary to use forceps with curved blades for pushing through the conjoined tendon, since it is difficult, especially in a patient with a fat thigh, to tilt the blades of a straight forceps forward through the tendon. I have not yet encountered a case where I could not perform the manœuvre of invagination with ease. The only obstacle has been in some cases the narrowness of the neck of the sac hindering the passage of the finger. This has been overcome without difficulty, as I have described. The features of the operation are that the crural canal is entirely denuded of peritoneum, and that there is no pit left at the site of the crural canal which may act as the commencement of another hernial sac. On the contrary, the invagination produces a prominence towards the abdominal cavity. The recurrence of the hernia is further hindered by the fixation of the invaginated sac to the conjoined tendon.

On one occasion recently, when I was operating on a case of double femoral hernia in a female patient, I felt, on passing my finger through the right crural canal into the abdominal cavity, a freely movable body of about the size of a nectarine. On opening the abdomen to remove what proved to be a pedunculated fibroid of the uterus I took the opportunity offered to observe the invagination of the sac from within the abdominal cavity, and the appearance was entirely satisfactory.

A similar method may be used in cases of direct inguinal hernia by invaginating the sac upwards and inwards through the outer border of the rectus abdominis muscle. In one case upon which I operated with excellent result—viz., in a case of right direct inguinal hernia in a man who also had a femoral hernia on the same side—I invaginated the sac of the inguinal hernia through the rectus and the femoral sac through the conjoined tendon. The two sacs thus crossed one another obliquely.

Manchester.

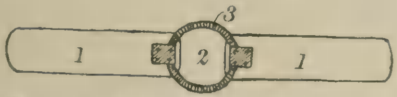
A TREATMENT FOR PROLAPSUS ANI IN YOUNG CHILDREN.

BY WILLIAM GEMMILL, M.A., M.B., CH.B. EDIN., F.R.C.S. ENG.,
LATE DEMONSTRATOR OF ANATOMY, UNIVERSITY OF EDINBURGH.

IT must be clearly understood that the following method deals entirely with the prolapse *per se*, and is not concerned with the exciting causes of that condition, local and general, which must in addition receive their adequate and special treatments. This method of retaining a prolapsus ani in a young child was first tried more than two years ago. It was used without much hope of success in a case of complete prolapse which had resisted all the ordinary methods of retention, including strapping of the buttocks; consequently it was with considerable surprise that I heard the report on the following morning that no prolapse had occurred in the interval. Since this first case the method has been used in several other cases of varying degrees of severity and always with immediate relief of the condition.

The considerations which led me to attempt this treatment were as follows. Normally, when the child defæcates he assumes a position in which the forces accessory to the expulsive contraction of the great bowel (the main factor in defæcation) may act to greatest advantage. The thighs are flexed and pressed on the anterior abdominal wall. The spine is curved with concavity forwards, the pelvis tilting, so that the iliac crests almost reach the costal margins. The position thus assumed of itself decreases the capacity of the abdominal cavity, but it also is a position in which the abdominal muscles, contracting to great advantage and with great force, still further decrease that capacity. Furthermore, when the thighs are flexed on the abdomen two additional results are obtained; firstly, the soft parts of the buttocks and thighs are removed from the region of the anus, thus a great support to the pelvic floor and anal canal is withdrawn, and the anus, instead of being a deeply embedded hidden orifice, comes to lie on the surface without support; secondly, the skin and subcutaneous tissue round the anal orifice are partly stretched, and the external part of the external sphincter is also stretched and put into a disadvantageous position for contracting efficiently. Hence it is evident that the normal position for defæcation is entirely satisfactory for the exercise of that function, and for the same reasons is favourable to the occurrence of prolapse, decreasing as it does the abdominal capacity, increasing the pressure within, and at the same time weakening the supports of the outlet.

These accessory forces, while of great advantage in defæcation in normal health, are of decided disadvantage in the treatment of prolapse, and especially is this the case when the prolapse is complete, in which type the accessory forces are doubtless the chief expelling factors. The principle then in treatment is to remove these forces as far as possible, and to bring about a condition in which the abdominal capacity responds passively to the decrease in contents brought about by the evacuating contractions of the large bowel, and is not actively decreased by the strength of the accessory forces. This is attained simply by preventing the flexion of the thighs and spine. A straight wooden splint, well padded and covered with mackintosh, is applied to the back of the child of a length to reach from the neck to the heels, and the child is fixed to the splint by two bandages, one round the thorax and the other round the lower limbs. More recently I have been using a similar splint with a hiatus in the region of the anus bridged by a circle of iron, as shown in the diagram. This allows defæcation without soiling of the splint, and also easy access for such local treatment as cold douching, &c. The result obtained is that the extended position of the child prevents the action of the accessory forces in great part, for the abdominal muscles are placed at a disadvantage for contracting. This position also prevents the decrease in abdominal capacity from flexion, as explained above. Hence evacuation takes place almost entirely from the muscular action of the great bowel. The removal also of the natural support which the soft parts give to the anal canal and sphincters is prevented, and the splint itself gives additional local support by pressing on the soft parts of the buttocks, from which it follows that the hiatus must not be too large, a condition in which this local pressure would be lost.



Sketch of splint for treatment of prolapsus ani. 1. Wooden splinting. 2. Hiatus for evacuation and local treatment. 3. Iron circle screwed to splint.

The relief which this method gives is immediate, the bowel remaining in the abdomen after reduction from the beginning and no prolapse occurring even during defæcation, for which the splint must not be removed. The advantages are efficiency, simplicity, and a minimum amount of trouble in the management of the child, who soon becomes quite comfortable and happy. The splint may be retained as long as is necessary for the child to regain health, for the sphincters to retain tone, and for a normal condition of the parts to return.

The Infirmary, Cleveland-street, W.

A CASE OF DELAYED CHLOROFORM POISONING.

BY H. P. FAIRLIE, M.D. GLASG.,
ANÆSTHETIST TO THE ROYAL AND WESTERN INFIRMARIES, GLASGOW.

THE following case of delayed chloroform poisoning is of interest for two reasons: (1) its late onset and (2) its rapid course.

The patient, a young woman aged 24, spare and rather nervous, was admitted to a nursing home on June 29th, 1914. During the two days which elapsed before operation her temperature was about 99° F. and her pulse about 80 per minute. Her heart and lungs were normal. The urine was acid and clear, had a specific gravity of 1030, and contained neither albumin nor sugar. On July 1st a laparotomy was performed; double tuberculous pyosalpinx was found, along with diffuse tuberculous peritonitis in the pelvis. During manipulation one Fallopian tube ruptured. Both were removed, and the wound was closed with drainage. The administration of the anæsthetic commenced at 3 P.M. and lasted for 38 minutes. Chloroform was administered throughout, during the first nine minutes on a Schimmelbusch mask, and then by the Vernon-Harcourt inhaler. Owing to the patient's nervousness the induction was protracted and three drachms of chloroform were given on the mask. Thereafter the anæsthesia was well maintained by the Vernon-Harcourt inhaler at 2 per cent. until five minutes before the end of the administration, when 1·8 per cent. sufficed; 5½ drachms of chloroform were given by the inhaler. The anæsthesia was satisfactory, with complete relaxation. On return to bed the patient's condition was good, the pulse 100 per minute and of good volume. During the next two days she progressed favourably, and with the exception of pain and attacks of hiccough made no complaint. Thirty-six hours after operation she vomited a small quantity (about an ounce) of brownish fluid. Forty-eight hours after the operation the dressing was stained and the wound dressed. A dose of castor-oil was ordered five hours later, but when an attempt was made to administer it at 8 P.M. on July 3rd—i.e., 53 hours after operation, the patient refused it, clenching her teeth and behaving in a peculiar manner. Although no characteristic symptoms appeared till next morning, when vomiting commenced, this seems to have been the first indication of the presence of acidosis, and during the night of July 3rd she seemed dull and stupid. Sixty-five hours after the operation vomiting of small quantities of brownish, coffee-ground fluid commenced and continued at frequent intervals. The patient was now comatose. Bicarbonate of soda and glucose were ordered in four-hourly doses per rectum, but no improvement resulted. The coma deepened, and along with this the face flushed and the pupils dilated, a decided odour of acetone appeared in the breath, and traces of acetone and albumin were found in the urine. Seventy-two hours after the operation Cheyne-Stokes respiration developed, the patient gradually sank, her temperature rose to 105·8°, and death took place nine hours later, about 24 hours after the onset of acidosis. A post-mortem examination was not obtained.

This case, although presenting many of the typical features of delayed chloroform poisoning, is of interest from the fact that definite symptoms did not develop for considerably more than 48 hours after the administration. Buxton[1] gives the usual time of onset as from 12 to 42 hours, and Hewitt[2] from 10 to 48 hours after anæsthesia. After the onset of symptoms the case ran a very rapid course, persistent vomiting commencing only 16 hours before the end. Owing to the employment of the Vernon-Harcourt inhaler the amount of chloroform administered was small relative to the length of anæsthesia, the importance of which Buxton[3] emphasises.

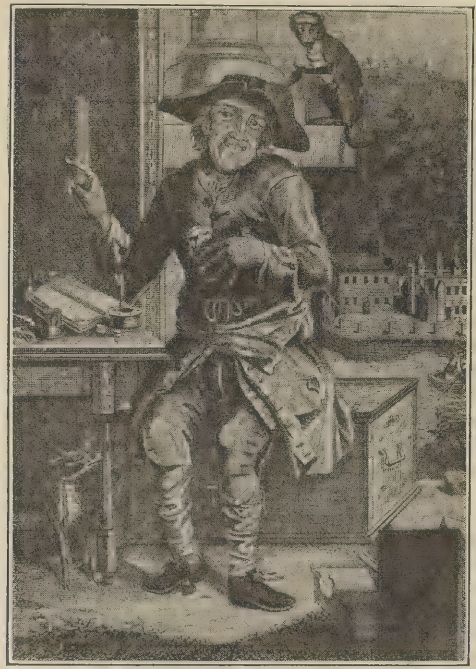
Glasgow.

A CASE OF ACROMEGALY 200 YEARS AGO.

BY LEONARD MARK, M.D. DURH.

IN the early Georgian period there lived at Scarborough a man named Richard Dickinson, of whom it is recorded that the singularity of his figure contributed to bring him into great notice among the gentry and others who visited Scarborough Spa, where he followed the double occupation of shoe-cleaner and vendor of gingerbread. He did not escape the notice of painters and poets of his time, and there are not less than seven original resemblances of him preserved by different artists, and copies of the same innumerably multiplied.

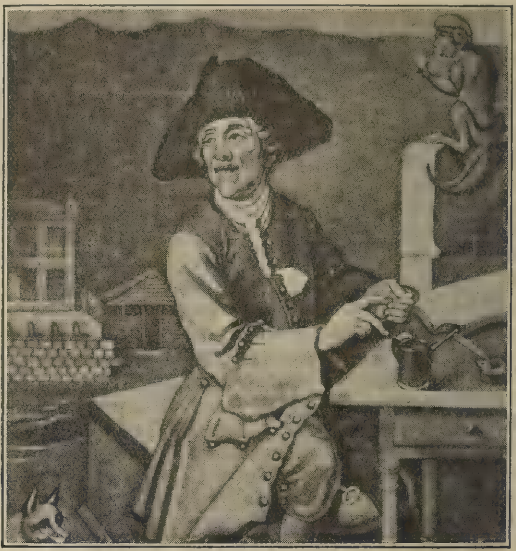
FIG. 1.



Richard Dickinson. (From a print dated 1726.)

Dr. Everley Taylor, of Scarborough, who is well known for the great interest he takes in all local and antiquarian matters, was reading "Acromegaly: a Personal Experience," when his attention was drawn to the fact that some of the peculiarities of this rare disease were to be found depicted in these portraits of Dickie Dickinson, and that we may have here the earliest representations of an acromegalic to be found in England. Some of the features of the disease are repeated in several of the pictures, so that it cannot be due to accident or faulty drawing if the various artists display these several peculiarities.

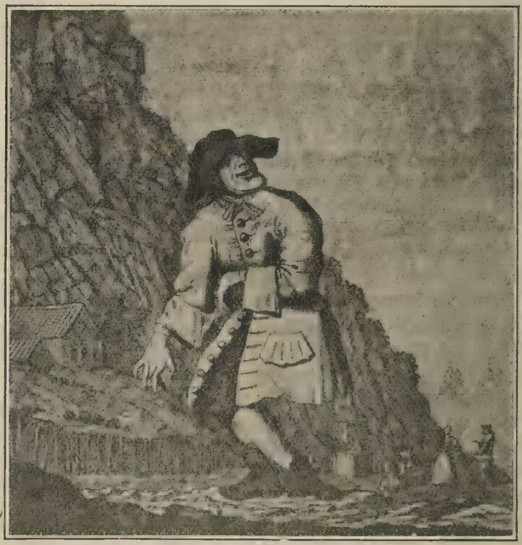
FIG. 2.



"Richd. Dickison." (From a contemporary mezzotint.)

We find the striking acromegalic facies in Fig. 1 The most obvious peculiarity is the very large lower jaw, depicted in five of the prints. This is accompanied by lengthening of the face and pronounced naso-labial folds. In one picture (Fig. 3) the marked prognathism gives the face the peculiar curve, concave from above downwards. In all the pictures the lips are large and prominent, leaving the mouth open and the teeth conspicuous. The massive chest with broad shoulders and the neck

FIG. 3



"Mr. Richard Dickinson of Scarborough Spaw."

[2] Sir Frederick Hewitt: Anæsthetics and their Administration, p. 639.

[3] Loc. cit.

buried between them, seen in Fig. 3, is a well-marked peculiarity, the one generally represented in *Punch*. The other symptoms which give the disease its name (acromegaly, big ends) are to be found in the large hands and feet in some of the pictures. The fingers are increased in length but not in breadth (Pierre Marie's *type en long*) (Fig. 2). In two pictures the feet are large and everted. The knock-knee and the bent-up condition of the lower extremities seen in all the pictures is due to some paralysis. The patient has probably in childhood suffered from rickets. He really seems to suffer from a variety of complaints, including some rheumatic affection of his left hand. The ulnar deflection is well depicted. (Fig. 1.)

The writer is indebted to Mr. Meredith T. Whittaker, J.P., of Weaponness Park, Scarborough, for the loan of five pictures and for the trouble he has taken in kindly supplying information about this curious individual. Mr. Whittaker has a very large collection of pictures and prints connected with Scarborough, and being most interested in the fact that possibly the earliest representations of a rare disease, only recognised of late years, are to be found at Scarborough, he has been good enough to write:—

> I send you five portraits of Dickinson. I think the etching best answers your purpose. I have the companion to it framed showing Dickie seated on his chest and his head tilted sideways, which displays the enormous length of his jaw. Probably the pictures vary on account of the portrait being drawn at different periods of the disease. I do not know the date of the etching. I have a copy of the one by Virtue; this was issued in 1725.
>
> Dickie had a trip to London, and it was probable on that occasion when he was painted.
>
> Settrington, who was a local bookseller, published a portrait of him in 1726, which I send. The two mezzotints are rare and one is in excellent preservation. These appear to me to be copied from Hysing, although the position is altered. Dickie was born in 1670; he was appointed as governor of the Spa in 1700, and had charge of the lavatories. He was probably of a low type of mind of an immoral age. According to the pictures his house was one of good class, and I have seen it recorded that it was showily furnished. The landslide of February, 1737–8, would cause his property great damage, and he apparently never got over the shock, and he died some time in 1738. His age would be 68.

It is interesting to think that we have here, perhaps, the earliest representation of an acromegalic to be found in England. Some earlier ones have been recognised on the continent—for instance, the portrait of a "giant" at the court of the Elector of the Palatinate, Frederick II., preserved in the Ambras-Schloss in the Tyrol, painted life size in 1553 by his court painter.

Another of still earlier date, of special interest at the present moment, is a carved figure of a woman, dating from the thirteenth century, which was placed high up on one of the flying buttresses of Reims Cathedral. This statue has been described as pointing out in a striking way the physical characteristics of acromegaly. As it stood on the north side of the cathedral, which was the one which suffered least from the early bombardment, there were hopes that it had been spared. At the moment of writing, however, the account of a renewed bombardment of Reims leaves one little hope that this interesting relic of the past, after weathering the storms of seven centuries, is not now to be reckoned amongst the innocent victims who have fallen before the spread of German Kultur.

Oxford-terrace, Hyde Park, W.

TRIGGER FINGER, ITS CAUSE AND MECHANISM.

BY ADONIRAM B. JUDSON, M.D.

A PROFESSIONAL man, 76 years old, had an attack of arthritis in the fingers of both hands in June, 1913, with resulting trigger finger in the proximal phalangeal joint of the middle finger of the right hand, with swelling and deformity, and stiffness of the joints of the middle and ring fingers. These results are still present. Motion past the right angle in either flexion or extension develops a painful snap or jerk. This may be described as a momentary hesitation, followed by a sudden acceleration. The jerk is more severe after the joint has been undisturbed for some time, and especially on waking in the morning. After it has been repeated a number of times for experiment or observation it is painless and comparatively slight. It is never entirely absent. When the hand is quiet there is no pain except what is felt in chronic arthritis on pressure or when motion is forced beyond the point of comfort. Many of the uses of the hand are interfered with. A pencil cannot be sharpened in the usual way by flexion and extension of the fingers. It also impedes writing and sewing. A woman thus affected said that a needle in her fingers seemed as large as a pencil. Other manual movements are at times brought to a sudden stop in a surprising, inconvenient, and more or less painful way. The momentary pain is sometimes very severe.

Cases of this kind have been occasionally reported, and they have given rise to an extensive "literature" devoted largely to cause and mechanism. The peculiar action of a trigger finger resembles that seen when a pocket-knife is opened or shut. Movement is smooth till a square shoulder at the near end of the blade presents an obstacle which retards motion till a certain point is reached when motion is accelerated with a jerk. A counterpart of this obstacle may be found perhaps in a node on an articular surface where it would cause the halting action of a trigger finger. In the construction of a knife, however, an important feature is present which is absent from the anatomy of the hand, and that is the strong steel spring concealed in the handle of the knife. It produces positive pressure between the surfaces composing the metallic joint. If the spring were absent, or if its place were taken by a strip of some inert substance like cork, there would be no jerk, and shutting and opening the knife would be perfectly smooth. While there is nothing very closely resembling a steel spring in the hand or forearm, still we may find in muscular action a force which draws the surfaces together and creates a pressure comparable with that produced by the steel spring.

The fingers require not only delicacy and swiftness, but also strength. Small in bulk and weight, and far removed from the point of resistance in the inertia of the trunk, they still are endowed with great strength. Their power comes from important groups of muscular fibres assembled in the mass of the forearm. The long tendons of one set, the flexor sublimis, are inserted in the bases of the second phalanges. They make pressure on the articular surfaces, especially those of the nearest joint, the affected one in the case here reported, pressure augmented by the pull coming from the other group, the flexor profundus, whose tendons pierce those of the sublimis to be inserted in the distal phalanges. These tendons are bound to the phalanges by fibrous sheaths, and as they lie close to the bones and parallel with them a large part of their force is expended in pressing the articular surfaces together, the residue being given to moving the joint.

Motion is doubtless impeded by intra-articular irregularities in other parts of the body where joint surfaces are held in contact by the static resistance of circumarticular ligaments and to some degree by the dynamic influence of muscular contraction. No joints, however, but those of the digits are subject to the exceptionally great pressure of powerful muscles acting through tendons lying parallel to, and in close contact with, long bones. It is clear that when digital muscles are in action they concentrate on small articular surfaces pressure as positive and distinct as that made by the steel spring of the pocket knife.

After witnessing the dissection of a normal hand, by the kindness of Dr. Gallaudet, it appeared to me that the node present on the radial side of the base of the second phalanx of the middle finger of the affected hand might extend into the joint, where it would project as an obstacle on the palmar edge of the articular surface at the base of the phalanx. At this point it would be in apposition, when the joint is at a right angle, with the rounded lateral articulating condyle on the radial side of the head of the proximal phalanx. It is evident that when these two eminences, one abnormal and the other normal, pass each other, as they do when the joint traverses a right angle, they must, when pressed together by muscular contraction, experience a momentary hesitation followed by an acceleration of speed such as is seen in trigger finger. That there may be cases which do not have their origin in arthritis is suggested by the personal experience and research of my frinds, Dr. Weir and Dr. Abbe.

It is surmised that as the flexors are stronger than the extensors the jerk of trigger finger would be more severe in flexion than in extension. This is found to be the case. And further, it is found that the jerk is lessened or absent when passive is substituted for active motion. These and other experiments are interesting and sustain my proposition to a certain extent, but they are wanting in scientific accuracy and their results are not constant. Aside from these experimental observations the presence of unusual pressure between the joint surfaces when voluntary motion is made by the fingers and the probable presence of a node on one of the surfaces give sufficient warrant to the following proposition. In trigger finger an obstacle of arthritic origin on one of the articulating surfaces is surmounted with momentary hesitation followed by a jerk or sudden acceleration of speed, as the joint moves under the exceptional pressure which voluntary action interposes between the articular surfaces of the digital joints.

X ray views have been taken in this case, but they fail to show any notable change in the bone. Ordinary inspection, however, shows swelling and deformity, with a projection on the radial side of the base of the second phalanx of the middle finger. The joint is an eighth of an inch wider at this point than its fellow of the other hand. Dissection would probably reveal surface irregularity. It is to be hoped, however, that a necropsy will not be proposed in the immediate future, as the joint herein described is part of the still good right hand of the author.

There has been no local treatment except by a gutter splint of sheet aluminium applied with a single strip of adhesive plaster to keep the joint extended at night. At the end of a year the jerk is less marked, but pain and stiffness continue and involve the metacarpo-phalangeal joint. Persistent catharsis has been maintained with oleum ricini, and as a result, perhaps, no other joint of the body has been attacked by the infection which is held to be the cause of chronic multiple arthritis, an affection intractable and as yet not well understood.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Cases.—Spontaneous Gastro-enterostomy.

A MEETING of this section was held on Dec. 11th, Sir FREDERIC EVE, the Vice-President, being in the chair.

Dr. ALEXANDER MORISON showed a case of Præcordial Thoracostomy for Heart Disease. The patient, a boy aged 16, was stated to have been in good health and capable of athletic exercise until Christmas, 1913. He had played football weekly from October till late in December. He then became breathless and had severe palpitation. No history of rheumatism or scarlet fever was obtainable. He was admitted to hospital in February, 1914, with tachycardia, irregular action of the heart, breathlessness, and a mitral systolic bruit. The area of cardiac dulness was much increased; powerful heaving of left ribs and cartilages from the fourth to the sixth and movement of the sternum were noticed. He was rendered comfortable by rest and taking tincture of digitalis, but without any diminution of thoracic movement, and was discharged in April feeling comfortable. He was told to return if again distressed, for præcordial thoracostomy. He did so in May and was again admitted. The operation was performed by Mr. Mower White in June, when $4\frac{1}{2}$ in. and $5\frac{1}{2}$ in. of the fifth and sixth ribs and cartilages respectively were removed. No costopericardial adhesions were found. Since then he had been comfortable, but still required tincture of digitalis. The object of the operation was to relieve the enlarged heart of the labour of raising the chest wall as well as driving blood.

Dr. ARTHUR F. HERTZ showed a case of Cardiac Achalasia (so-called cardiospasm). The woman, aged 36, had complained for ten years of pain under the lower part of the sternum and a choking sensation under the upper part whenever she ate. She had always had an impression that her food had difficulty in getting into her stomach. About two years ago she fell from a ladder and hit her chest; since then she had constantly vomited part of the food after every meal, and it came up quite undigested, but mixed with a considerable amount of mucous saliva. During the night she frequently woke owing to regurgitation of her evening meal through her nose; the food was now sour, especially if several hours had elapsed since the meal, in contrast to the food brought up during meals, which was never sour. The condition became steadily worse until nine weeks ago, when she ceased to be able to keep down any solid food at all. During the three days before she was seen six weeks ago, no food had been retained at all. An X ray examination showed that the whole œsophagus was dilated, the obstruction being at the cardiac orifice of the stomach. There was violent peristalsis in the œsophagus, but the food only trickled with extreme slowness into the stomach. The condition was diagnosed as cardiac achalasia, and a mercury tube was passed. This met with no obstruction at the cardia, and the patient had since been able to retain her food, unless it was insufficiently masticated, by passing the tube immediately before each meal. The term "achalasia" (α, not; χαλάω, I relax) was coined for him (Dr. Hertz) by Sir Cooper Perry to replace the term "spasm," which was incorrect for the following reasons: (1) Hypertrophy of the cardiac sphincter is never observed after death, even if the obstruction has lasted for 20 or more years, although long-continued spasm would necessarily lead to hypertrophy; (2) the mercury tube passes without any sense of obstruction through the cardia, which would be impossible if a spasm were present; (3) the mercury tube can be withdrawn without any difficulty, whereas it would be grasped by the sphincter were cardiospasm really present. He believed that the condition was due to the absence of the normal relaxation of the cardia, which should occur when each peristaltic wave reached it. Similarly, many cases of so-called pylorospasm were due to pyloric achalasia, and ileo-cæcal achalasia was the most frequent cause of ileal stasis.

Dr. HERTZ and Mr. C. H. FAGGE contributed the notes of a case of Spontaneous Gastro-enterostomy with subsequent perforation and recovery after operation. The patient was a woman, aged 48, who for six years had suffered from indigestion, the pain occurring from one hour to an hour and a half after food. Vomiting and hæmatemesis had been present. In 1913 she had been treated for gastric ulcer. In 1914 she developed sudden violent pain in the epigastrium, and the diagnosis of perforated gastric ulcer was made. At the operation Mr. Fagge found an opening between the stomach and jejunum—i.e., a gastro-jejunostomy had taken place. Secondary perforation had followed. The parts were left *in situ* and protected by suturing the jejunum to the stomach and omentum. She had since left the hospital perfectly well. X rays showed that the stomach was small and emptied after 20 minutes through the gastro-jejunostomy opening, very little bismuth passing through the pylorus.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.

A MEETING of this section was held on Nov. 27th, Mr. T. H. KELLOCK, the President, being in the chair.

Dr. E. B. GUNSON showed a child with Tooth Erupted at Birth. It was a male infant, one of twins born at full term. The left lower median incisor was erupted at birth. On the tenth day the tooth, which was then loose and attached only by the gum, was removed as its presence interfered with suckling. The right lower median incisor had then also appeared through the gum. The child was well developed and presented no other abnormality. The fellow twin was normal.

Dr. J. PORTER PARKINSON showed a case of Friedreich's Disease with Spastic Phenomena. The boy, aged 13 years, was the ninth of 10 children; his mother's eleventh pregnancy terminated in a miscarriage. For three years before the patient's birth the mother was very depressed and almost insane. The patient was a full-term child, healthy at birth, but before the age of 3 years had scarlet fever, measles, chicken-pox, whooping-cough, and diphtheria. He began to walk at 3 years, but never walked well, and was never very intelligent. He was now a fairly well-grown boy with a rather unintelligent expression. Speech indistinct, slurred and syllabic. Gait spastic, uncertain; slight difficulty in turning. Romberg's sign negative. The legs were held stiffly, the muscles hard and well developed; the foot showed marked pes cavus with some equinus; the great toe was hyperextended at the proximal joint, and the extensor tendon very prominent. There were marked knee and ankle clonus and an extensor plantar reflex. The arms were in every way normal, grasps equal, no ataxy of arms or legs. Cranial nerves normal, no nystagmus, and no changes in the fundi. The spine was normal, and the bladder and rectum not affected. Sensation normal. No similar disease in the family.

Mr. L. BROMLEY showed a case of Tumour of the Upper Extremity of the Femur in a boy aged 12 years. A swelling of the right thigh had been noticed for the previous seven or eight weeks. He complained of pain in the right leg, especially after walking; on some days the pain was so severe that he was unable to walk. When the patient was aged 3 years he was said to have fractured the right femur; since then he had had intermittent pains of an aching character, which had increased lately. On examination a hard swelling of the upper third of the right femur was felt. There was no definite margin, and no heat or tenderness. Movements at the hip-joint were free. A skiagram showed an endosteal growth of the femur. On exploration the bone was found to be expanded and covered by normal periosteum; a thin layer of compact bone surrounded a mass of cartilage which had entirely replaced the medullary cavity. Microscopic examination showed pure chondroma, and there was no suggestion of malignancy.

Dr. T. R. WHIPHAM showed two cases of Heart-block. 1. A female infant, aged 2 years and 2 months. The child was born at full term, and had always been backward. The first tooth was not cut until the age of 9 months, and she did not sit up until she was a year old. Up to the present she has not walked or talked. She was a well-nourished child with a good colour, and presented no clubbing of the digits. The pulse was slow, full, and regular. The right side of the heart in the skiagram appeared to be enlarged, and the outline of the organ was almost globular. All over the præcordium a loud systolic bruit was audible, the maximum intensity being between the apex and the left sternal border and extending up to the pulmonary area. The heart rate was slow, but it varied from time to time, the lowest recorded being 48, and the highest 80. The child was first admitted into the Evelina Hospital with whooping-cough and slight bronchitis, but even then the heart was only beating on the average about 64 per minute, and at times the respirations were quicker than the pulse. Paroxysms of coughing, moreover, caused very little, if any, acceleration of the heart. No cardiac symptoms had at any time been observed. An electrocardiogram showed a perfectly regular 2:1 heart-block. There was a polycythæmia of 8,400,000 red corpuscles per cubic millimetre and the hæmoglobin value was 110 per cent. 2. A girl, aged 12 years. With the exception of measles at an early age she had had no illness. Six years ago it was first noticed that she had a slow pulse, but it was not until 18 months ago that any cardiac symptoms occurred; since then she had complained of pain around the heart on exertion. She was well-grown and showed no cyanosis. The pulse was slow, usually between 50 and 60 per minute, and slightly irregular in rhythm; the extreme rates noted had been 40 and 64. The heart was considerably enlarged, especially on the left side, as seen in a skiagram, and there was a heaving impulse in the fifth interspace well outside the nipple line. A systolic bruit was audible with its maximum intensity in the fourth interspace near the sternum; occasionally at the apex and a little outside a slight diastolic whiff had been heard. The second sound in the pulmonary area was at times reduplicated. An electrocardiogram and a polygraph tracing showed a marked dissociation between the auricular and ventricular beats, and an irregularity in the rhythm of the latter. A subcutaneous injection of atropine sulphate (1/60 gr.) caused the ventricular rate to be increased from 40 to 60 per minute, but did not affect its arrhythmia. The patient at times had complete heart-block with pulse slow and regular, and at times incomplete heart-block of high grade (3:2, 2:1, and mixed) which produced an irregular pulse.

Dr. WHIPHAM also showed a case of Diabetes Insipidus with Infantilism. The patient, a boy aged 4 years, was the sixth child in a family of eight, all of whom had been backward. He was bottle-fed and cut his teeth late, and did not walk until he was 2 years old. He could not yet talk. Height, 2 ft. 9 in.; weight, 1st. 6½ lb. About two years ago he started to pass a large quantity of urine and to complain of great thirst and to lose flesh. On admission to hospital he was passing from 200 to 900 c.c. of urine per diem, but under general treatment and rest the maximum had been 300 c.c. in a day. The urine was very pale, of low specific gravity, and contained no abnormal elements.

Dr. J. D. ROLLESTON showed a case of Giant Nævus. The patient was a girl, aged 7 years, showing a pigmented hairy and warty nævus and numerous accessory nævi. The principal nævus started in front, slightly internal to the anterior border of each sternomastoid, and passed backwards, occupying each posterior triangle of the neck and extending 1 inch below each clavicle. Behind it extended as a continuous sheet upwards to the external occipital protuberance, outwards to the acromion process and downwards to the spine of the twelfth dorsal vertebra, where it ended in a tapering point. The pigmentation of the nævus was dark brown, interspersed with vitiliginous patches, and was interrupted at the periphery by linear areas of unpigmented skin running obliquely downwards and outwards. The skin of the pigmented area was sharply marked off, but was not raised above the level of the normal skin, and showed no sensory changes. There was no spina bifida. The nævus was covered by downy hairs mostly of a light colour, except in the interscapular region, where they were darker. Several warty growths of the same colour as the pigmented skin were present in the cervical and upper dorsal area of the nævus, the largest being situated just below and to the left of the external occipital protuberance. In addition to the principal nævus other nævi were scattered over the rest of the skin. The largest were situated on the right thigh and right buttock. Most of the lesions situated on the limbs were hairy, but a few were smooth. A few smooth nævi were present on the soles, but the palms were free. The fewest and smallest lesions were on the face. There was no hereditary or familial history of similar lesions, but there was a definite history of a maternal impression. During the third or fourth month of pregnancy the mother had been frightened by a black and tan dog which had tried to bite her husband, and had thrown her arms over her head. She had anticipated that the child would be marked, though her medical attendant had tried to persuade her to the contrary.

Dr. **BERNARD E. MYERS** showed a case of Splenomegaly improved by antisyphilitic treatment. The patient, a boy aged 1 year 11 months, was admitted to the Royal Waterloo Hospital last June (then aged 18 months) for diarrhœa and wasting. His weight at that time was 9 lb. 8 oz. His father died two years ago as the result of an accident, and his mother died from phthisis when the patient was a year old. At the age of 4 months the patient had measles. When first examined in June he presented a very wasted appearance all over. His abdomen was distended. The child was listless, anæmic, of an earthy complexion, and with a sunken fontanelle. Some signs of rickets were present. There were about six motions in the 24 hours. The temperature and pulse were normal on admission, while the respiratory rate was slightly raised. The spleen was enlarged, moderately firm, and extended to just below the level of the umbilicus. The edge of the liver was felt 1½ inches below the costal margin. No albumin was discovered in the urine, which was acid and of specific gravity 1020. The Wassermann and von Pirquet reactions were both positive. The blood count on June 17th was :—

Red blood corpuscles	3,040,000 per cubic millimetre.
Hæmoglobin	44·0 per cent.
Leucocytes	14,000 per cubic millimetre.
Polynuclears	35·8 per cent.
Lymphocytes	54·8 ,,
Large mononuclears	6·0 ,,
Transitionals	1·4 ,,
Myelocytes	2·0 ,,
	100·0 ,,
Normoblasts	3·0 ,,
Megaloblasts	1·2 ,,

A provisional diagnosis of splenic anæmia of infancy was made. Hydrarg. c̄ creta, ½ gr. t.d.s., together with a bismuth mixture, was given. Only slight improvement being noticeable, this treatment was stopped in favour of mercurial inunction over the region of the spleen. The diet consisted of milk in various forms, arrowroot, meat-juice, and small quantities of brandy. Distinct and steady improvement followed the inunctions. The diarrhœa gradually ceased and the child's appearance became healthier. The spleen was noticeably smaller week by week. On Sept. 17th he was put on syrup. ferri iodidi, 10 minims t.d.s. On Oct. 9th a blood count showed—

Red blood corpuscles	5,640,000 per cubic millimetre.
Hæmoglobin	90·0 per cent.
Leucocytes	10,000 per cubic millimetre.
Polynuclears	30·2 per cent.
Lymphocytes	53·6 ,,
Large mononuclears	12·0 ,,
Transitionals	4·2 ,,
	100·0 ,,

Red blood corpuscles appeared normal. During his first two months in hospital his temperature was raised on and off. His present weight is 1 st. 4 lb. 12 oz. He looks well and is now a cheerful, intelligent child, and takes ordinary diet. Both spleen and liver are still a little enlarged. He has suffered from catarrh of the lungs, but this is now much better. On Nov. 20th his blood was again examined by Dr. Leathem and his report showed :—

Red blood corpuscles	6,130,000 per cubic millimetre
Hæmoglobin	100·0 per cent.
Leucocytes	16,600 per cubic millimetre.
Polynuclears	57·4 per cent.
Lymphocytes	19·6 ,,
Large mononuclears	16·8 ,,
Transitionals	3·0 ,,
Eosinophiles	3·2 ,,
	100·0 ,,
Normoblasts	1·0 ,,

Red blood corpuscles appeared normal in size and shape. Wassermann reaction positive, although not strongly marked.

Mr. **PHILIP TURNER** showed a case of Double-retained Testicle in which the left testicle was transplanted to the right side of the scrotum and the right testicle to the left side. The patient, a boy aged 12 years, was admitted to hospital for double inguinal hernia with imperfectly descended testicles. Both testicles, which appeared to be ill-developed, could be palpated in the inguinal canals ; they had never descended below the external abdominal rings. The following operation was performed: The right sac and spermatic cord were exposed by a small incision through the external oblique just above the internal abdominal ring. The hernial sac was separated from the vas and veins as far as the internal ring, and there ligatured. By traction on the distal part of the sac the testicle was drawn through the small incision in the external oblique. The sac was then ligatured immediately above the tunica vaginalis and removed. The remains of the gubernaculum were then transfixed, ligatured, and divided, the ends of the suture being left long. The testicle, enclosed in the tunica vaginalis, was now, except for its connexion with the spermatic cord, quite free. An incision about an inch long was then made over the front of the left side of the scrotum. The free ends of the ligature transfixing the gubernaculum were then seized with Spencer Wells forceps, which were then introduced through the incision in the external oblique, pushed along the inguinal canal, through the external ring into the right side of the scrotum. The ends of the forceps were then made to impinge against the scrotal septum. A small incision was now made on the forceps through the wound in the left side of the scrotum. The forceps carrying the ligature were pushed through to the left side and the ends of the ligature secured. The forceps were then withdrawn, and by pulling on the ligature the right testicle was drawn along the track made by the forceps along the inguinal canal through the scrotal septum to the left side of the scrotum. Both wounds were then closed. The patient was readmitted two months later and the left testicle was then transplanted to the right side of the scrotum by a similar operation. No sutures were necessary for the fixation of the testicle in its new position, the contraction of the opening in the septum preventing its return and exercising a gentle continuous traction which was absent in the ordinary method of orchidopexy.

Mr. **TURNER** also showed: 1. A case of Double Retained Testicle in which the right testicle only had been transplanted. He proposed to transplant the left testicle later. 2. A case of Seasonal Enlargement of the Parotid Glands. The patient, a boy aged 14, had had painful enlargement of both parotid glands every spring and autumn for the last nine years. The other salivary glands were not affected, and the boy showed no other abnormality except that he was unduly sensitive to cold.

Dr. **F. J. POYNTON** and Mr. **H. MORRISTON DAVIES** showed a case of Cleido-cranio-dysostosis in which the removal of the outer part of the imperfect right clavicle relieved severe symptoms from pressure on the brachial plexus. The patient, a girl aged 20 years, had been reported originally by Dr. E. I. Spriggs in THE LANCET.[1] In December, 1913, she was shown by Dr. Poynton at the Clinical Section for an opinion as to the best method of treatment of severe symptoms, pointing to pressure on the right brachial plexus. Her work as a dressmaker had been interfered with by severe shooting pains down the inner side of the arm and over the front of the chest. There was marked loss of power in the right hand, and much circulatory disturbance. When the shoulder was depressed the right pulse was diminished in volume, a sign which assisted in the exclusion of syringomyelia, a condition which has been described in association with this form of dysostosis. Mr. Davies removed the outer fragment of the clavicle, and when the patient left the hospital there was already clear improvement. She had been completely free of the severe neuralgic pains, her hand had recovered power, and she had resumed her occupation. The only complaint now was of a dull ache in both shoulders, brought on by the long hours during which she sat in a position sewing over her work that tended to make the shoulders "over-stoop." This was relieved by sitting up with the shoulders braced back, and was of an entirely different nature to the former trouble, which was caused by the inner end of the outer fragment of the right clavicle hitching under the outer end of the inner one.

---

[1] THE LANCET, Dec. 7th, 1907, p. 1599.

Dr. Frederick Langmead showed a case of Achondroplasia, Pseudo-rachitic. The patient, a female infant aged 6 months, was first seen when 9 weeks old. Many signs of rickets were present, but the legs were disproportionately short compared with the body, and the finger tips with arms extended reached only to just below the crest of the ilium. On this account the provisional diagnosis of achondroplasia had been made, although the head, face, and hands had not the characteristic appearance.

Dr. J. L. Bunch showed a case of Keratosis Follicularis Spinulosa in a boy aged 4. Lesions had first been noticed about 14 months ago on the neck and later on the arms, back, and abdomen. They consisted of small acuminate papules which were more perceptible to the touch than to the eye. There were no inflammatory phenomena.

Dr. C. O. Hawthorne showed a case of Acholuric Jaundice. The patient, a girl aged 1 year and 3 months, was a first born child, said to be jaundiced from birth. She had jaundice, considerable enlargement of the spleen, some enlargement of the liver, no bile in her urine, and normal stools. Blood examination showed white cells, 14,500 (polymorphs, 44·8; small lymphocytes, 47·2; large mononuclears, 6·8). The blood serum contained bile pigment.

Dr. Hawthorne also showed a case of Paramyoclonus Multiplex. The patient, a boy aged 6 years, was said to have been jerky since birth. There were frequent, quick, clonic contractions most marked in the abdominal muscles, but visible also in the shoulders, upper arms, thighs, cremaster muscles, and to some extent in the face. The contractions were bilateral, but the two sides were not always affected simultaneously. There was no family history of rheumatism, chorea, or epilepsy.

SECTION OF LARYNGOLOGY.

Exhibition of Cases.

A MEETING of this section was held on Dec. 4th, Dr. G. William Hill, the President, being in the chair.

Sir StClair Thomson demonstrated a case of Early Malignant Disease of the Larynx, shown at the last meeting, and referred to some details of the operation of laryngofissure which he had performed under chloroform after preliminary injection of eudrenine. He had injected 10–15 minims of cocaine solution into the trachea before making the opening, thus abolishing the spasm of the glottis. No Hahn's tube was used. as he had found that an ordinary tracheotomy tube was sufficient for such cases. He referred to the difficulty in removing the whole of the disease, especially from the arytenoid and subglottic regions, and showed sections from the case. As it was evident that some of the growth had not been removed, he performed a second operation ten days after the first, and the patient had made an excellent recovery.—The President pointed out that the removal of the arytenoid was liable to lead to complications, especially to difficulty of swallowing, and Dr. Dan McKenzie stated that he had had similar experiences.—On the other hand, Mr. Herbert Tilley was of opinion that excision of the arytenoid, whether partial or complete, caused no trouble whatever.—Dr. J. Dundas Grant added that wherever possible the upper part of the arytenoid should be left.—Dr. W. Jobson Horne recalled the fact that there had been very free mobility of the vocal cord in this case, and suggested that the disease might be a pachydermia rather than malignant disease.—In this connexion Mr. Stuart-Low stated that he thought it was important to palpate the larynx with the finger because in pachydermia the tissues were softer than in malignant disease.—Sir StClair Thomson, in his reply, believed that as a general rule removal of the arytenoid led to complications. He stated that he had had no fatality after 20 laryngofissures. He did not think it possible to palpate beyond the upper opening of the larynx.

Sir William Milligan showed three Foreign Bodies Removed from the Bronchi. The first was the case of a boy, aged 4, who accidentally inhaled a damson stone. Sharp dyspnœa followed, of which several attacks with spasmodic coughing occurred during the ensuing ten days. X ray examination proved negative. On admission to the Royal Infirmary slight bronchitis with diminished entry of air into the left lung was noted. Examination was made under general anæsthesia. There was a sudden arrest of respiration. Rapid tracheotomy was performed and artificial respiration. Recovery ensued. The child was put back to bed for half an hour, again anæsthetised, the tracheotomy tube withdrawn, and a bronchoscope tube passed. The damson stone was seen in the left bronchus with pointed end protruding (specimen shown). It was successfully recovered with forceps. Rapid recovery followed. In the second case, a female, aged 35, accidentally sucked in a carpet-tack from her mouth. There was a sudden and severe paroxysm of dyspnœa. During the following four days several slight attacks of dyspnœa and coughing fits ensued. She was admitted to the Royal Infirmary eight days after the accident. (An X-ray photograph of the tack *in situ* was shown.) Under general anæsthesia the tack was grasped, but on traction being made the forceps slipped off. Many unsuccessful attempts at extraction were made. The patient was kept quietly in bed for three days. Vapor benzoin co. was used every two hours. The patient was again anæsthetised and removed to the X ray dark room. The fluorescent screen was employed and forceps made to grasp the tack. Withdrawal was again unsuccessful owing to the forceps not holding the stem of the tack sufficiently firmly. Many more unsuccessful attempts at extraction were made. At the suggestion of Mr. Barclay (radiographer to the Royal Infirmary) an attempt was made to twist the tack round upon its own axis. After much trouble this was accomplished, and the tack was immediately withdrawn by grasping its head (specimen shown). Despite prolonged manipulations on these two occasions no systemic disturbance followed and the patient left hospital upon the third day in perfect health. In the third case a coin was readily seen impacted about the level of the sterno-clavicular joints. It was *in situ* for ten days. Removal was made with forceps. The œsophageal wall was intact. Rapid recovery ensued (specimen shown). These cases demonstrated (1) the tolerance of the tissues under certain conditions; (2) the advisability, if not necessity, of not relying upon the results of radiography; and (3) the value of the fluorescent screen as an aid to the removal of foreign bodies from the lung.—Mr. Tilley said that the results of radiography in these cases were often unreliable, and drew attention to the value of instantaneous photography.—Sir StClair Thomson, Dr. D. R. Paterson, and Dr. Irwin Moore discussed the difficulty of holding a foreign body with long forceps, and agreed that as soon as the object had been grasped it was advisable to withdraw the bronchoscope and forceps together rather than to attempt to bring the body through the tube.—Sir William Milligan added that it was advisable to perform tracheotomy in young children so that a wider tube and shorter forceps could be used.—The President referred to the value of combined X rays and bronchoscopy in operations of this kind.

Sir William Milligan also showed a case of Angiofibroma of three years' standing arising in the maxillary antrum in a patient aged 17. Kuhn's per oral intubation tube was passed and the mouth packed with gauze. Lateral rhinotomy was performed. Several attempts to remove the growth failed in consequence of the furious hæmorrhage. Finally, the cavity was tightly packed and saline administered. Forty-eight hours afterwards the packing was removed, when there was again very severe hæmorrhage. A radium emanation tube (50 mgm.) was inserted into the middle of the growth. No return of hæmorrhage occurred, and there was rapid retrogression of growth. Three weeks afterwards there was no trace of growth, but a dense, firm, fibrous mass was attached to the posterior antral wall (microscopic section shown). The general and local condition of the patient was now excellent. Sir William Milligan drew attention to the doubtful malignancy of nasal growths, and stated that although the microscopical section demonstrated tissue that appeared to be innocent the case was clinically malignant.—The PRESIDENT, Mr. TILLEY, and Dr. DUNDAS GRANT said that such cases could often be cured by radium.

Mr. TILLEY showed a Choanal Polypus with an ulcer on its posterior surface of the size of a shilling, the latter leading to some difficulty in diagnosis until the growth had been removed. In many such cases there was no recurrence, but if the polypus reappeared twice it was essential to open the antrum.—Sir WILLIAM MILLIGAN suggested that the ulcer might have been self-inflicted.

Dr. J. F. G. ELPHICK showed a patient with a Retro-pharyngeal Swelling in whom the Wassermann reaction was positive. It was agreed that the disease was probably syphilitic.

Dr. C. W. M. HOPE showed a patient from whom he had removed by stripping from underlying perichondrium a Tuberculoma of the Nasal Septum. The whole of the right side of the septal mucous membrane for a distance of 2 inches from the vestibule and almost up to the roof was found affected. Cartilage and bone were not touched. The floor of the nostril and inferior meatus were found affected and treated in the same way. Also affected anterior two-thirds of superior turbinal was removed. Sections and mass from the septum were shown.—Mr. D. VINRACE and others referred to the difficulty of distinguishing between lupus and tuberculosis.—Sir STCLAIR THOMSON had seen a similar case in which the disease lasted for 17 years, during which time it spread from the nose to the pharynx, later to the larynx, and finally to the lungs.

Dr. MCKENZIE showed some soft metal tubes for insertion into the nose after submucous resection of the nasal septum which greatly relieved the discomfort caused by nasal obstruction.

Mr. H. CLAYTON FOX showed a case with Malignant Disease of the Tonsil and Pillars of the Fauces, which was interesting because in its first stages it appeared to be a simple tonsillitis with abscess. Later the growth appeared and was microscopically papilloma, though the case was probably malignant.

Dr. L. H. PEGLER showed a Superior Maxilla from an aged female with an abnormal malar antrum behind the true maxillary cavity.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

The Threshold of Disease.

A MEETING of this section was held on Nov. 20th, Dr. WALTER G. SMITH being in the chair.

Professor J. A. LINDSAY, the President, read an address entitled "The Threshold of Disease." Dealing with the problem of early diagnosis, he chose four subjects for special consideration: (1) endocarditis, (2) gastric cancer, (3) disseminated sclerosis, and (4) pulmonary tuberculosis. 1. In acute rheumatism, endocarditis was extremely common in adults and almost the rule in children. Muffling of the first sound at the apex, slight increases in cardiac dulness, and arrhythmia were very suspicious signs. Prolonged rest in these cases was most important. 2. In a patient of 50 who had previously had a good digestion, and who was not suffering from renal or hepatic disease, cancer might be suspected if he took a dislike to flesh meats, exhibited some loss of flesh and debility, and occasionally vomited. The absence of free HCl was the rule. Hæmatemesis was rarely an early symptom. 3. Taken as a whole, the following symptoms were highly suggestive of early disseminated sclerosis—transient disturbance of vision, impairment of bladder control, paræsthesia of one or more limbs, diminution of abdominal reflex, loss of tone of sphincter iridis, giddiness, and emotional instability. 4. No tests other than finding tubercle bacilli in the sputum were convincing in making a diagnosis of incipient phthisis. Calmette's, von Pirquet's, and Arneth's, and the opsonic index method had a very limited value. We were thrown back on clinical examination. Early and very suggestive symptoms were—loss of flesh, slight afternoon pyrexia, cough, and acceleration of the pulse. The first physical signs in the chest were auscultatory, and consisted of hardness or weakness of the breath sounds. Crepitations were later. Slight hæmoptysis and night sweats were very significant. X rays were of some value, but the interpretation of the skiagram was very difficult.

Dr. SMITH referred to the vexed question as to whether signs elicited by percussion or auscultation gave earliest evidence of incipient pulmonary tuberculosis. He was inclined to believe those elicited by percussion did so.

Dr. J. F. O'CARROLL was not at all sure, when all was said and done, that the early diagnosis of disease had not as many disadvantages as advantages. There was something to be said for keeping going on as long as possible and trying to be guided by nature. As to pulmonary tuberculosis, he rather thought the debate between the value of percussion as against auscultation was a debate as to individual experience, each observer generally being impressed by the method by which he got the most information.

Dr. H. C. DRURY thoroughly agreed as to the supreme value of early diagnosis. He thought if the matter was reasoned out it would be seen that percussion would yield a very late sign as compared with auscultation. He had always believed that long before anything like crackling was discovered the roughening of the expiratory sound was the earliest departure from health.

Dr. T. G. MOORHEAD considered that a distinction should be drawn between the early diagnosis of phthisis on which one would start treatment and the early diagnosis from which statistics might be compiled with fairness.

Professor LINDSAY, in reply, said that for all statistical work in connexion with phthisis the line ought to be drawn between cases in which bacilli were found in the sputum and those in which they were not, because in one class there could only be a suspicion of the disease, whereas in the other there was positive proof.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 17th at the Royal Infirmary, Dr. A. Manknell being in the chair.—Dr. F. W. Eurich read short notes on three unusual cases of Bacillus Coli Infection. The first was that of a workman who was supposed to have strained himself whilst lifting a heavy weight. Shortly afterwards double orchitis set in which could not be accounted for in the ordinary way. Bacteriological examination of the urine revealed bacillus coli in great abundance. In the second case a man, aged 58, presented himself with swelling of both testicles, with a history of a knock two years previously, since which time he had had periodic attacks of orchitis. In this case also a bacteriological examination of the urine revealed enormous numbers of bacillus coli. The third case was that of a woman, aged 45, who on Dec. 13th, 1913, had what appeared to be a slight conjunctivitis of one eye. Four days later there was some iritis. After 10 days' treatment her condition improved, but on Jan. 23rd she had a relapse together with slight irritation of the bladder. On Feb. 3rd the condition was much worse—retinitis and turbidity of the vitreous. On Feb. 16th bacillus coli was discovered in the urine, and a vaccine prepared. In a fortnight recovery was complete.—The cases were discussed by Dr. R. A. R. Lankester, Dr. W. Mitchell, Dr. F. W. Goyder, and Dr. Manknell.—Dr. Eurich then replied.—Dr. Mitchell showed numerous X Ray Photographs of great interest.—Dr. Goyder read a paper on the Treatment of Infantile and Other Forms of Paralysis in General Practice. Treatment, he said, is based on the principle enunciated many years ago by Hugh Owen Thomas and rediscovered by Robert Jones, of Liverpool.[1] No paretic muscle has a chance of recovery so long as it remains overstretched. Hence the first rule of treatment is to fix the limb in such a position that the paretic muscles are relaxed. Operations such as tenotomy may be required for this purpose. Plaster-of-Paris splints may be used, or, better, the much lighter celluloid splints. Walking should be encouraged with the patient in the splints. It is impossible to say how much improvement will take place after this simple manœuvre. Even after many years of paralysis the improvement is often astonishing. No operations for tendon grafting should be undertaken until many months after the application of the splints. If as soon as possible after the initial attack such splints are applied, since the paretic muscles never become overstretched, recovery from paralysis, if it is going to take place at all, is certainly hastened. This principle can be applied to nearly all forms of paralysis, irrespective of their cause—e.g., wrist drop from lead or musculo-spiral injury or Erb's obstetrical paralysis. In Little's disease the element of spasm is also present, but wonders can be worked if the child has any intelligence by simple fixation in the over-corrected position for some months after simple tenotomy of the adductors or tendo Achillis according to the region affected. In many cases no tenotomy is required. More complicated procedures should be reserved for cases in which simpler ones have proved insufficient. Hence, apart from operation, much can be done by the general practitioner, especially in the early stages of infantile palsy. Treatment, though tedious, is most interesting, and often well repays the trouble taken.

---

[1] THE LANCET, May 30th, 1914, pp. 1515, 1551.

LIVERPOOL MEDICAL INSTITUTION.—At the last meeting of this institution Dr. E. W. Hope, the President, from the chair, drew attention to the Belgian Doctors' and Pharmacists' Relief Fund, and a committee was formed to work with the executive of that Fund.—Mr. G. P. Newbolt read a short paper on Appendicitis in the Elderly. He reported three cases, and emphasised the fact that appendicitis did occur in those over 60 more commonly than was generally recognised, and also that perforation not infrequently took place without causing any serious initial symptoms.—The paper was discussed by the President, Mr. W. T. Thomas, and Mr. F. Larkin.—Mr. A. A. Bradburne read a short paper on Bilateral Optic Neuritis due to sphenoidal sinusitis, in which the left sixth nerve was involved; the vision of the left eye was somewhat impaired with severe occipital pain; spontaneous discharge of pus from the sphenoidal sinus was followed by gradual improvement. Total absence of any trouble in the nose pointed to sinus infection.—Captain C. Thurstan Holland read a paper on the X Ray Treatment of the Wounded at Fazakerley Hospital, fully illustrated by lantern slides. He carefully described his methods for arriving at the locality of a foreign body in the tissues illustrated. There were numerous lantern slides showing the destruction of bone and the character of the injuries produced by bullets and pieces of shell.—The President opened the discussion.—Dr. Barclay described the instrument which he had devised to facilitate rapid estimation of the depth of foreign bodies and deprecated indiscriminate removal of bullets.—Dr. J. Oram described another method based on the series of curves.—Captain Arthur W. C. Evans referred to his experiences in the Boer War, and compared them with his present work at the Fazakerley Base Hospital. He was strongly in favour when removing the bullet from the fleshy parts of making a free incision in order to save the muscles as much as possible. The muscles should be separated rather than cut across. The bullet of to-day made a much more serious wound than the bullet of the Boer War.—Captain Holland, in his reply, advocated conservative surgery when dealing with comminuted fractures.

ROYAL INSTITUTION.—Professor C. S. Sherrington, M.D., F.R.S., the new Fullerian Professor of Physiology at the Royal Institution, will deliver a course of six lectures at the institution on Muscle in the Service of Nerve, at 3 P.M., on Tuesdays, Jan. 19th and 26th, and Feb. 2nd, 9th, 16th, and 23rd, 1915.

LADY MINTO'S INDIAN NURSING ASSOCIATION.—In the annual report of this association, dated Nov. 23rd, attention is called to the difficulty in obtaining trained nurses for the work in India. The majority of the nurses who had been selected for service with the association afterwards withdrew their names and joined various bodies for tending the sick and wounded in connexion with the war. Reference is also made to the urgent need for funds owing to the falling off in subscriptions. The address of the association is 91, York-street, Westminster, S.W.

Reviews and Notices of Books.

Diseases of the Stomach.

BY CHARLES G. STOCKTON, M.D. London: D. Appleton and Co. 1914. Pp. 774. 65 illustrations. Price 25*s.* net.

THIS book is written primarily for the use of general practitioners by a clinician who has had long experience as a keen observer of the diseases of which he treats. To make it more comprehensive he has obtained the aid of various authorities on pathology, laboratory methods, radiography, and physical methods of treatment. In his introductory chapter he discusses the position of the "internist" (a term which the author employs to denote the specialist whose province is the gastro-intestinal tract) who should share with the general practitioner the domain of the diseases of the stomach. He rightly describes as nihilistic the view that gastric digestion is unimportant and unnecessary—a view which we think is the result of the technical skill that has been attained by the modern surgeon and the experimental physiologist. After reading his introduction we agree that the surgeon and the morbid anatomist see only few of the diseases of the stomach, and then but the advanced stages of disease. The study of diseases of digestion includes not only organic disturbances, but the far more frequent functional disturbances, and must fall into the special province of the general practitioner and the "internist."

In the earlier chapters are discussed the anatomy and physiology of the stomach and methods of examination. Amongst these we note special descriptions of the "string test," together with duodenal alimentation, a method which the author's own observations lead him to conclude to be of some value in curing cases which otherwise would require surgical relief. We do not think, however, that the method has been as yet widely introduced in this country. In the chapter on radiography there are some useful diagrams from actual photographs. He deals fully with dyspepsia, but points out rightly that the modern attempt to classify such cases on a basis of some special manifestation of gastric disturbance, such as the variation in secretion or in motility, is in practice not feasible, although occasionally there may be such a dominant feature. Discussing the various theories that have held sway concerning the cause of dyspepsia, he comes to the conclusion that symptoms almost identical may be induced by disturbance of the nervous system, by auto-intoxication, by metabolic failure, or by gastritis, and he discusses these in detail.

There is some truth in the adverse comment on the practice of exploring the abdomen for the purpose of diagnosis and the removal of the appendix as a routine procedure, or even, if this fails, draining the gall-bladder. A large variety of dyspepsias are discussed under the headings of clinical manifestations, such as eyestrain, disturbance of special senses, and diathesis. The chapters on peptic ulcer are specially worthy of note and include various prescriptions and general methods of treatment. Dealing with gastroptosis the author illustrates fully the physical methods of treating such. In addition to all the ordinary diseases usually dealt with he devotes a chapter to syphilis of the stomach and another to arteriosclerosis involving the vessels of the stomach, with illustrative cases;

then vomiting, abdominal pain, and tenderness are discussed in detail. He also has a special chapter on the œsophagus, and concludes with a brief account of alimentation. We note on page 45 what is evidently a misprint, where it is stated that five or ten *minutes* elapse between the two deglutition sounds heard on auscultation.

The book is good and up-to-date, and we can safely say that the material dealt with has been put forth in an unbiassed fashion which will appeal to both the general practitioner and the specialist.

Outlines of Chordate Development.

By WILLIAM E. KELLICOTT, Professor of Biology in Goucher College. London: Constable and Co., Limited; New York: Henry Holt and Co. 1914. Pp. 471. Price 10*s.* 6*d.* net.

THIS volume may be taken as the natural sequence and corollary to that on general embryology, and in it the student is introduced to the study of chordate development through the embryological history of amphioxus, as it affords, in simple diagrammatic style, the essentials of early chordate ontogeny.

The whole development of amphioxus falls into four general periods: 1. Production of the germ cells, including oögenesis and spermatogenesis and spawning. 2. Embryonic period, from fertilisation to the opening of the mouth—a very rapid phase, occupying about 36 hours at normal seasonal temperatures of the water. 3. Larval period, from the opening of the mouth to the cessation of pelagic life and the assumption of a burrowing habit—a period about three months—during which the parts marked out in stage 2 are further elaborated. The larva is then about 3·5 mm. long. 4. Adolescent period from stage 3, or the "critical stage," to sexual maturity, a period marked by histological differentiation and the gradual appearance of adult characteristics. Each period is described with ample detail. Following this is a rather full account—166 pages—of the early and later development of the frog, the latter dealing with organology. The frog is important zoologically, not as a central type of any large group of chordates, but as a transitional form connecting the lower and higher groups of craniata. The account is admirably clear, and does not err on the side of giving too many details.

In discussing the development of the chick, first the embryonic membranes and appendages are considered and then the organology. These chapters are relatively brief, and emphasis is laid on the embryonic membranes, and upon the early phases of development which represent the most frequent modifications of the type of chordate development. This is an admirable and attractive exposition of the subject, while the numerous and carefully drawn illustrations greatly help to elucidate the chief morphological changes. The final chapter on the mammals includes only those phases of development that are of chief interest to the general student—e.g., the earlier stages in the formation of the embryo, the establishment of its relations through the placenta with the maternal organism, the development of the embryonic membranes and appendages, and also the development of the external form of the human embryo.

This treatise on chordate development is as lucid, succinct, and attractive as that on general embryology, and both works should prove most valuable to students of the fascinating subjects with which they deal.

LIBRARY TABLE.

A Text-book of Organic Chemistry. By A. F. HOLLEMAN, Ph.D., F.R.A. Amst., Professor ordinarius in the University of Amsterdam. Edited by A. JAMIESON WALKER, Ph.D. Heidelberg, assisted by OWEN E. MOTT, Ph.D. Heidelberg, with the coöperation of the author. Fourth English edition, partly rewritten. London: Chapman and Hall. 1914. Pp. 622. Price 10*s.* 6*d.* net.—The favourable reception of this book is evidenced in the issue of a fourth edition within ten years of its first publication. In previous notices we anticipated its success owing to its clear presentation of both facts and principles and to the intelligible system of classification adopted. The book has received careful revision, necessitated by the advances made, chiefly in the application in organic chemistry of physicochemical methods, while the section on tautomerism has been entirely rewritten, and that on the benzene derivatives rearranged. It is a trustworthy book, and whilst dealing with a great and complicated subject keeps well within the bounds of a text-book.

Mediterranean Winter Resorts. By EUSTACE REYNOLDS-BALL, F.R.G.S. Vols. I. and II., bound together. Seventh edition. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1914. Pp. 635. Price 5*s.* net.—This guide-book to the principal health and pleasure resorts on the shores of the Mediterranean appeals not only to the pleasure-seeker but also to the invalid. To this end it contains special articles written by resident English physicians on the principal invalid stations. Vol. I. covers only the northern shores of the midland sea, the French, Italian, and Levantine Rivieras, South Italy and Sicily, and Southern Spain. First a series of travel routes is given. Then come descriptions of the principal resorts under the above sections, followed in each case by practical details as to hotels, cafés, restaurants, golf-links, places of entertainment, churches, hospitals, banks, conveyances, and a directory of English doctors, dentists, and chemists, with much other useful information. Vol. II. covers on a similar plan Morocco, Algeria, Egypt, and the Mediterranean islands. Each volume has a substantial index, and appendices include the list of members of the Anglo-American Continental Medical Society, legal notes, hints for winter residents, notes on winter in the West Indies, and India as a winter resort.

Medical Nursing. By A. S. WOODWARK, M.D., B.S. Lond., &c. London: Edward Arnold. 1914. Pp. 324. With 68 illustrations. Price 4*s.* 6*d.* net.—This is a useful little book, containing all the information needed by a nurse in regard to the illnesses from which her patients may be suffering. The instructions are clear and precise, there is no verbiage, and the illustrations are good and sufficient. That, however, on p. 18, showing the proper way of raising a patient, does not give the position of the arms correctly, and is not according to the (correct) instructions in the text. Antiseptics are not accurately defined either on p. 32 or on p. 79. Is not "the juice of half a lemon" rather a large quantity to take with each dose of, say, cod-liver oil? Our last criticism is that a bunion is not a corn (p. 270). On the whole the book fulfils its purpose very well.

Ueber den Mechanismus der Oxydationsvorgänge im Tierorganismus. Von Dr. med. LINA STERN, Privatdozent der Physiologie an der Universität Genf. Mit 12 Abbildungen in text. Jena: Gustav

Fischer. 1914. Pp. 61. Price 2.20 marks.—This is a lecture that was delivered in Berlin in 1913, and it contains the results of investigations by the author and Professor Battelli on the oxidation processes in the organism. It is divided into two parts, of which the first deals with the now well-recognised oxidases, such as the alcohol, uric acid, xanthin, tyrosin, and phenol oxidates. Next, what are called "oxidones" are dealt with. These are insoluble catalysers which are present in animal tissues and which possess the property of accelerating oxidation in different substances. The second part deals in an attractive manner with the respiration of the tissues, or what is called "internal respiration." This is a useful and suggestive lecture on an obscure but all-important chemical problem.

JOURNALS AND MAGAZINES.

The American Journal of Tropical Diseases and Preventive Medicine, Vol. II., No. 4.—This number opens with an editorial by Dr. Isadore Dyer on the cause of pellagra, in which it is stated that "the number of cases now in the United States and the number of deaths that result from the disease each year is simply appalling." The two main views as to the origin of the malady are discussed—namely, whether it is a deficiency disease associated with a faulty dietary or a specific infection due to a micro-organism. Some account is given of experiments on monkeys, the results of which, however, have been hitherto inconclusive. There are five original articles, the first of which is on the propagation of amœbic dysentery in animals and the recognition and reproduction in animals of atypical forms of the disease, written jointly by Dr. A. W. Sellards and Dr. W. A. Baetjer. It is said that the inoculation of infective material from virulent, and also from distinctly avirulent, cases of amœbic dysentery directly into the cæcum of kittens has given practically 100 per cent. of infections as compared with the usual result of about 50 per cent. of positive infections when virulent material is fed or injected per rectum. Major Weston F. Chamberlain, of the Medical Corps of the United States Army, contributes a paper, with illustrative plates, on spirochætæ and fusiform bacilli in various lesions in the Philippines. A further note upon the occurrence of endamœbæ mortinatalium as a human parasite is supplied jointly by Dr. A. J. Smith and Dr. F. D. Weidman, from the laboratories of pathology in the Medical School of the University of Pennsylvania. Dr. H. Windsor Wade and Dr. Houston L. Staring of New Orleans contribute an article on bubonic plague, with details of the study of a typical case which occurred during the recent outbreak in that city. Tuberculosis in tropical countries, and the necessity for greater effort to prevent it, are discussed by Dr. Isaac W. Brewer. "Mal de bocha," or tropical infectious stomatitis, is the subject of a contribution by Dr. Nathan Barlow, based on his experience of the disease in Northern Mexico. This affection is apparently transmitted by direct or indirect contact, and Dr. Barlow regards a rather delicate spirochæta as the most probable cause. The usual notes and comments, with reviews of current literature, complete an interesting number of the journal.

The British Dental Journal.—The issue of Dec. 1st of this journal contains a paper by Mr. John Humphreys on the Evolution of the Human Dentition. He traces the development of tooth forms through the various geological periods, discussing in detail the primates. Reference is made to the teeth of prehistoric man, and he states that "at the end of its long period of evolution the human dentition has almost returned to the point from which it started and reverted towards the primitive anthropoid arrangement as in parapithecus." There are two presidential addresses, the one by Mr. W. de C. Prideaux dealing with the antiquarian beauties of the county of Dorset.

ERRATUM.—In the review in THE LANCET for Dec. 5th, p. 1306, of Dr. Arthur Thomson's book, the title was erroneously given as "Outlines of Biology." It should have been "Outlines of Zoology."

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) URODONAL; (2) FILUDINE; (3) JUBOL; AND (4) GLOBEOL.

(J. L. CHATELAIN, PARIS. LONDON AGENTS: HEPPELL AND CO., 164, PICCADILLY, W.)

WE have received four interesting pharmaceutical products from the laboratories of M. Chatelain, Paris. 1. Urodonal is described in many clinical accounts as an effective solvent of uric acid, and accordingly it is regarded favourably in the treatment of arthritis, rheumatism, and uric acid troubles. It is a combination of three definite compounds, each of which is a recognised solvent of uric acid. They are methyl-glyoxalidine, quinate of diethylenediamine, and hexamethylenetetramine. The preparation occurs in an attractive granular effervescing form. 2. Primarily, the formula of filudine is designed for the treatment of hepatic disorder and in addition to thiocinnamate of caffeine contains liver and spleen extracts. These latter are claimed to stimulate the functions of the liver and more particularly its antitoxic activity. It has thus been employed in cirrhosis, hepatic colic, and diabetes. It has been used also in malaria. The formula is an interesting one and, organic extracts apart, cinnamic compounds are known to increase the supply of red corpuscles in the blood. 3. Jubol is also an interesting formula containing as a basis agar-agar with biliary extract and also extracts of the intestinal glands. It is regarded as a means for the rational treatment of intestinal stasis. It has been used, it is said, with excellent results in the treatment of muco-colitis, its action being certain but mild and unirritating. 4. Our examination of globeol pills confirmed the statement in regard to their novel composition. When extracted with cold water a fluid was obtained which showed the hæmoglobin spectrum. The solution coagulated on boiling, and small though definite quantities of iron and manganese were found. The formula is put forward as of value in the treatment of anæmia and neurasthenia.

TONALKA APERIENT WATER.

(IDRIS AND CO., LIMITED, PRATT-STREET, CAMDEN TOWN, LONDON, N.W.)

The composition of this water resembles that of certain well-known natural bitter purgative waters. There were present the sulphates of sodium and magnesium with some common salt and a small quantity of carbonate of soda. The total saline constituents amounted to 54·04 grammes per litre. According to our analysis these were made up as follows: sodium sulphate, 33·40 grammes; magnesium sulphate, 16·88 grammes; sodium chloride, 3·46 grammes; and carbonate of soda, 0·30 gramme. The therapeutic action of the water will be understood from this analysis. It serves as a mild and efficient purgative.

LUTROL.

(CORBYN, STACEY, AND CO., LIMITED, 673, COMMERCIAL-ROAD EAST, LONDON, E.)

Lutrol is an efficient antiseptic and detergent, being composed of a neutral soap and cresylic acid. The ingredients are carefully balanced so as to preserve a fluid without corrosive properties. We decomposed the preparation separating the soap from the cresols, and there were thus liberated exactly 50 per cent. of cresylic acid. It is, of course, well adapted for cleansing and sterilising work in surgical practice, and gives a clear solution diluted with water.

(1) URASEPTINE; (2) MERSALV; (3) IODEOL; AND (4) IODARGOL.

(M. BRESILLON AND CO., GAMAGE BUILDINGS, HOLBORN, LONDON, E.C.)

1. Uraseptine is, as its name implies, a urinary antiseptic, it is made up in a granulated form. The therapeutic constituents present are piperazine, urotropine, helmitol, and the benzoates of sodium and lithium. The presence of these latter is important in rendering the urine acid by the action of which urotropine or hexamethylenetetramine yields formaldehyde. 2. Mersalv is an ointment containing 10 per cent. metallic mercury amalgamated with a non-fatty but oily basis in a very finely distributed metallic state. It is prepared for the treatment of syphilis with mercury by the inunction method. 3. Iodeol preparations in various forms have for their basis colloidal chemical iodine and form an effective method of administering this element. Iodeol is prepared by suspending colloidol iodine in sterilised olive oil. It is used as an intramuscular injection, while another preparation (4), known as Iodargol, a viscid mixture containing colloidol iodine, is used for injection into the urethra. It is enclosed in ampoules and a special syringe is provided for the purpose.

LAGER BEER.

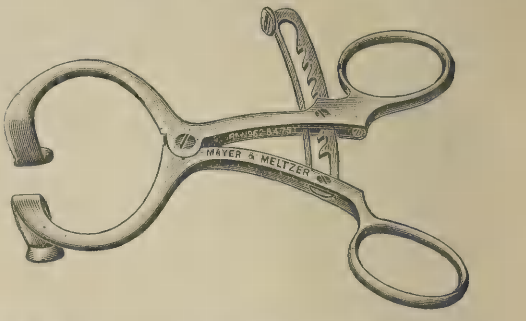
(THE PHŒNIX TRADING CO., 14B, GREAT MARLBOROUGH-STREET, LONDON, W.)

Two varieties of lager beer were examined, the one being light in colour and the other dark brown. They both showed the same alcoholic strength. The complete analysis of the light beer was as follows: alcohol by volume, 5·00 per cent.; malt extractives, 5·78 per cent.; volatile acidity reckoned as acetic acid, 0·09 per cent.; lactic acid, 0·25 per cent.; malt sugar, 1·04 per cent.; and mineral matters, 0·24 per cent. The analysis of the brown beer was as follows: alcohol by volume, 5·00 per cent.; malt extractives, 5·89 per cent.; mineral matters, 0·19 per cent.; volatile acidity reckoned as acetic acid, 0·09 per cent.; lactic acid, 0·22 per cent.; and malt sugar, 1·08 per cent. It will be seen that there is a general resemblance of composition between the two beers. They are both quite light alcoholic beers, and contain further a minimum of sugar. They have a flavour which may be described as "dry." We searched for objectionable preservatives, but without success.

New Inventions.

AN IMPROVED (DOYEN'S) MOUTH GAG.

Doyen's gag has some good points, or it would not be in general use; yet it also has bad ones, which I will enumerate thus: 1. The jaw of the instrument which happens to be upwards usually presses against the palate when the mouth is widely opened; this causes pain and occasionally injury. 2. The lower lip of the patient is liable to be caught between the incisor teeth and the lower jaw of the gag; this also causes pain and injury. Sometimes the patient suffers more from damage thus caused than from the surgical operation. 3. The milled head of the joint-screw projects to such an extent as to prevent close contact of the rubber face-piece (of the anæsthetist's apparatus) with the patient's cheek; this allows of the escape of gas or ether and consequently delays proceedings. 4. When the gag is widely opened the end of the rachet comes so close to the patient's mouth that it (like the milled screw-head) is liable to cause an escape of the anæsthetic; further, its shape renders it liable to tear the thin rubber air cushion of the face-piece. 5. The sharp saw-like rachet is quite exposed; consequently, when in order to remove the gag this rachet is released it is liable, through contraction of the stretched muscles of the patient's jaw, to be driven forcibly backwards and so lacerate the anæsthetist's finger, just as a saw would if drawn across it. Two practitioners have informed me that they have thus suffered. 6. The spring is forged solid with the rachet and occasionally breaks. This entails several days' deprivation of the use of the instrument while it is being repaired, and a cost of about 10*s.*



In the opinion of two anæsthetists who have used it the disadvantages referred to above have been overcome in the gag illustrated here. It was made to my designs by Messrs. Mayer and Meltzer, of Great Portland-street, London, W.

CHARLES J. HEATH, F.R.C.S. Eng.,
Late Surgeon, Hospital for Diseases of the Throat, Golden-square, W.
Devonshire-place, W.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., to-day (Friday, Dec. 18th), at 8.30 P.M., when a paper (illustrated by slides) entitled, "Tropical Problems in the New World," will be read by Dr. Andrew Balfour, C.M.G.

CIVIL AND MILITARY SANITATION IN THE TROPICS.—The second Chadwick public lecture was delivered by Sir Ronald Ross, K.C.B., F.R.S., at the London School of Economics on Dec. 11th. The lecturer first asked how far it was advisable or necessary for governments to develop sanitation, and pointed out that as a matter of fact sanitation could not be conducted by private individuals themselves, and must require the coöperated efforts of the authorities. The second question was what modifications in the ordinary apparatus of free government were demanded for sanitation; and the lecturer urged that it was unwise to bestow complete liberty of action as regards sanitation on very small municipal governments. He maintained that where the death-rate of such municipalities was above the average they should be called to account by superior governments, as had actually been done in the case of one municipality in the empire. His view was that very small municipalities, however desirous they might be to advance sanitation, seldom possessed enough men with sufficient knowledge of town management and hygiene to conduct these branches of administration with success. The third question was whether Government should develop research; and this, he said, was already answered by the Colonial Office and the India Office in the affirmative. Lastly, he pointed out that the head of every sanitary administration should be placed upon a footing equal to that of the head of every other great department, and should, if possible, be always given a seat on the local executive council. The next course of lectures will be given by Dr. F. M. Sandwith on War and Disease at the Royal Society of Arts on Jan. 15th, 22nd, and 29th at 5.15 P.M.

THE LANCET.

LONDON: SATURDAY, DECEMBER 19, 1914.

The Treatment of Wounds in War.

IN recent issues of THE LANCET we have printed some important communications on the treatment of the wounded in war, which originated in an address delivered before the Medical Society of London by Sir WATSON CHEYNE;[1] this week we are able to publish a contribution to the discussion from Sir ANTHONY BOWLBY which derives its great interest from the presence of the author with the Expeditionary Force as consulting surgeon. Broadly speaking, the question as promulgated at the Medical Society resolved itself into a debate as to what should be done to a recent wound in which septic germs have become lodged. Is it sufficient for us to prevent the access of further organisms by the application of an aseptic dressing, trusting to the *vis medicatrix naturæ* or the resistance of the tissues to deal with those germs which have already been admitted, or shall we endeavour by the use of antiseptic substances to destroy the invading organisms before they have time to penetrate the tissues bordering on the wound? This is no new question. It is that which presented itself to LISTER some 50 years ago, and it is that which he answered from the standpoint of knowledge then reached by his antiseptic treatment. When he recognised that the cause of suppuration in wounds was the presence of micro-organisms he endeavoured to destroy them by the application of crude carbolic acid, and the success of his endeavour demonstrated that it was possible at an early stage of the infection of a wound to remove the invading germs by chemical means. His first case[2] was one of compound fracture, a form of lesion which had up to that time been always followed by prolonged suppuration and severe septic symptoms. After the application of the carbolic acid the wound healed without suppuration and all signs of general sepsis were absent. This method of dealing with wounds, somewhat modified by its introducer as his experience widened, was employed by him during the whole of his active professional life, and it was followed with remarkable success by other surgeons throughout the world. Gradually, however, the idea arose that such a strenuous treatment of a wound must do great harm to the surrounding living tissues. The evidence in favour of this damage was by no means great, and the objection to the use of antiseptics in the wound was almost completely based on theory. The advocates of the aseptic method relied on theoretical considerations; it must be, they contended, harmful to pour a strong solution of carbolic acid into a wound, for the damage to the living tissues may be quite substantial.

Sir ANTHONY BOWLBY's letter supports the arguments employed by Sir WATSON CHEYNE, who advocated the maintenance of the Listerian methods in fitting circumstances, in a remarkably direct way. Of his experiences with the army Sir ANTHONY BOWLBY draws a picture which shows convincingly that it is upon antiseptic procedure much as LISTER laid down its principles that the treatment of wounds in war must depend. No one doubts that in the case of a deliberate wound made after the taking of elaborate precautions by an operating surgeon there is no need to employ antiseptics, for with care it is possible to keep the wound free from germs. But the case is utterly different when we have to deal with wounds which have already become infected. Here it is not possible with the very greatest care to prevent the multiplication of the germs which have already entered the wound and the absorption of these germs or their products. The application of an aseptic dressing over the wound will not and cannot affect the septic process going on within. When the wounded fighting man is seen within a few hours of the infliction of the injury it may be and often is possible to render the wound aseptic. In such cases the septic organisms are there; but they can be antagonised, and they may be overcome. And how seldom it happens that in war the wounds of the sufferer can be seen within a few hours; how frequently the soldier having incurred an injury of the sort most apt for sepsis abides long hours in an environment reeking with infection. We may all of us have known the tragic truth that no amount of forethought, skill, or devotion could spare our defenders these terrible risks, but Sir ANTHONY BOWLBY's simple forcible description of the conditions must make this more real to us than ever. "There seems to be an idea," he says, "that 'aseptic' surgery has been practised at the front, but as far as the clearing stations are concerned, this is entirely a misapprehension. I have myself never given up 'antiseptic' principles and treatment, and I was glad to find that in every clearing hospital antiseptics were always used." And he shows that the usual treatment must be in accordance with the Listerian routine.

As a matter of fact the separation of surgery into the completely aseptic and the completely antiseptic is rather academic. In spite of its disdain for chemical antiseptics modern aseptic surgery has not hesitated to employ a solution of iodine to sterilise the skin preparatory to surgical operations; but when we hear of wounds in action being treated by painting the skin with iodine and by applying an aseptic dressing, while nothing is done to the wound itself, we cannot endorse the reasoning which underlies. This may be aseptic surgery, but it is not wise. The case is, indeed, different when many hours have elapsed since the infliction of the wound; then the germs have had time to penetrate deeply into the tissues forming the sides of the wound, so that an antiseptic cannot follow them. What shall be done in such cases? The essential elements in the treatment here are the removal of disintegrated structure where the circumstances point thereto, and the employment of adequate drainage. It may be asked whether the employment of an antiseptic in a wound never damages the tissues. Certainly this does happen, but the damage inflicted on the tissues by one application of even a very strong antiseptic will do little mischief, and what mischief is done is rapidly repaired by the tissues. What is really harmful is the repeated application of even weak antiseptics to healing tissues. Many who would shrink from applying a strong solution of carbolic acid to a recent wound will not hesitate to irrigate a wound day after day with antiseptic solutions which can do little more than serve to irritate the parts. Sir Rickman Godlee prophesied recently that the time would come when some surgeon would rediscover Listerism. We cannot believe that such rediscovery will be necessary at any rate until our science takes some unforeseen step forward. As long as wars are conducted as at present Listerism will be the only sound method to follow in dealing with the wounded in the field. The pendulum has swung far in the opposite direction, but only to return. Sir Rickman Godlee quoted recently Lister's saying that if he should ever write a book on surgery he would choose as its motto the words of Psalm xxxviii., "My wounds stink and are corrupt, because of my foolishness." Much unnecessary sepsis exists to-day in civil practice because of the unwise neglect of the teaching of Lister. Sir Anthony Bowlby's vivid communication indicates how hopeless any other routine would be in military practice.

Quackery and a Ministry of Public Health.

THE Unqualified Practice Prevention Committee of the General Medical Council submitted recommendations at the recent meeting of the Council after it had considered the report of the Select Committee of the House of Commons on the subject of so-called patent medicines. These recommendations,[1] which were adopted by the Council, suggested that the approval of the Select Committee's report by the General Medical Council should be expressed under two headings. In the first place, there should be conveyed to the Lord President of the Privy Council an expression of the General Medical Council's complete agreement with the recommendations of the Select Committee; and in the second place there should be a representation to the Government, through the Lord President, of the necessity for the immediate creation of a Ministry of Public Health. It will be remembered that the Select Committee recommended that the administration of an improved, reconstructed, and coördinated law relating to the advertisement and sale of patent medicines should be entrusted to one department of State, and that this should be the "Ministry of Public Health, when such a department is created." The Select Committee considered the possibility of legislation to regulate the trade in patent medicines preceding the institution of a Ministry of Public Health, and suggested that the Local Government Board should undertake "meanwhile" the proposed departmental duties. The General Medical Council has now by resolution urged the desirability of proceeding first to create the department without waiting for this particular section of its probable future duties to be brought into being. This appears to be a wise and reasonable course, and it is to be hoped that the Government may be able to find the time and the occasion to carry into effect the advice of the representative body of the medical profession, charged with the standardising of our education and the proper maintenance of our statutory Register.

For the passage of controversial measures involving conflicting commercial interests there is not likely to be an early opportunity, and legislation on the subject of patent medicines will involve the disturbance of vested interests, whose representatives will certainly wish to secure a full hearing for their case, and to invoke protection wherever they can find it. At the present time a large number of Members of both Houses of Parliament are on active service, and are likely to remain so for many months—a fact which, combined with the other circumstances of a grave national position, renders it probable that only a very small amount of domestic legislation will be attempted in the near future. In the case of a large and flourishing trade, if not in most shapes a desirable one, no Bill affecting it is likely to be introduced at present, and neither the advocates of such a measure, nor its opponents, would wish to have it discussed under any unsuitable conditions. The formation of a Ministry of Public Health, however, is a different matter. It is not the result of a proposal made by the Select Committee on Patent Medicines, which has merely suggested the creation of certain duties for a State department, which naturally would be assigned to the Ministry of Public Health if it existed. It does not exist, but its creation has been asked for and desired for a long time by all interested in the national health and welfare. Incidentally it would be very convenient if, on the passing of a new law to regulate the trade in patent medicines, the department were there ready to carry it into effect, but the formation of the department has been urged upon other grounds. The formation of a new authority to supervise the carrying out of existing laws of great public importance, for which it would be specially adapted by its constitution and to which it would devote its undivided attention, cannot be deemed to be an innovation likely to create controversy or arouse opposition. The proposal should rather appeal to all anxious to promote business-like efficiency in matters of administration. Moreover, at this particular juncture questions of public health are arising out of conditions wholly abnormal, and which demand special attention and skilful handling. Huge camps of soldiers in training, and large bodies of recruits in towns and populous districts where no such incursions of population have been provided for, are a matter of grave concern for others besides the military authorities, and are not likely to become less so as winter progresses and as time goes on. Camps and other arrangements for the internment of aliens come into the same category, and meanwhile the civil population is deeply concerned in the maintenance of its public health. Soldiers returning from the front are not unlikely to develop infectious disease, and the general health of the nation during the coming year or years may not improbably be below the usual standard, though we may add that for various reasons the reverse may occur.

---

[1] THE LANCET, Dec. 5th, 1914, p. 1314.

In devoting itself to the maintenance of the public health in spite of adverse conditions the medical profession, considerably depleted by the absence of so many of its members from their usual duties, is likely to have an anxious period and one of strenuous work before it. Its members, therefore, and particularly those to whom the public health is a matter of official solicitude, would assuredly welcome the assistance and coöperation of a strong Government department in sympathy with their aims, and able to give its whole attention to furthering them. It is a hopeful sign that a committee such as that which was appointed to consider the case of patent medicines should have appeared almost to assume general assent to the proposition that a Ministry of Public Health ought, and is likely to be created. It has certainly also recommended the institution of administrative duties which would require important additions to be made to the personnel of any existing department, and would increase the responsibilities of the department named by the committee in an inconvenient degree should they be thrust upon it. We hope, however, that no necessity for this will arise, and that the representation made by the General Medical Council will receive prompt and serious attention from a Government whose preoccupations we fully recognise and whose devotion to duty is increasing.

ENTERIC FEVER AT BARCELONA.—There is at present a severe epidemic of typhoid fever at Barcelona—more than 20,000 cases, at the rate of 200 to 300 cases a day. The cause is said to be a contaminated spring, which is the main source of the drinking water-supply of the town.

Annotations.

"Ne quid nimis."

THE MEDICAL DIRECTORY, 1915.

THE regular appearance of the annual "Medical Directory," published by Messrs. J. and A. Churchill, has long since established itself as an event of important utility on which not only medical men, but many other classes of people and public officials, have come to rely as a part of the machinery of affairs. The first thing that strikes us in the seventy-first annual edition, that for 1915, just to hand, is the thinness in bulk of the volume. Seeking the cause of this we find that the useful numerical summary of the profession, given yearly on p. 2, is limited this year to the medical profession "in the British Isles." This reaches a total of 36,656. The total in the summary last year was 41,972, and the explanation is found in the fact that the tabulation last year included members of the profession resident abroad. The title page next indicates that the directory of registered medical practitioners "resident abroad" is now contracted in scope to those "resident in Europe and North Africa." This section, which no longer contains an alphabetical list of names, but only a local list (with detailed mention, however), occupies only 13 pages, as against 205 pages in 1914, which accounts in large part for the fact that the total number of pages in the Directory is only 1923, as against 2159 last year. Naturally in the present condition of affairs we can understand that Austria, Hungary, Germany, and Turkey are omitted. Probably in no case is any British medical man who may unfortunately happen to have remained in those countries able or even permitted to practise his profession. But what is of far greater importance is the omission of the large number of names in Asia, South, West, East and Central Africa, the American continents and adjacent islands, and Australia, the local lists of which in the Directory for 1914 occupied 22 out of the 23 pages in the local list of practitioners resident abroad. While making every allowance for the present cataclysmic state of affairs, with the inevitable permanent changes that must ultimately ensue, we earnestly hope that the missing portion will be restored next year, and that the editors will address themselves at once to that task. From some correspondence that appeared in our columns in the autumn of 1913 it is evident that efforts were then in contemplation to find a means of reducing the bulk of the Directory; but any attempt to effect this end by materially contracting its sphere of utility we feel convinced will be suicidal. The medical profession has long been proud of the complete and accurate service rendered to it by Churchill's "Medical Directory," and anything that would imperil its usefulness would be greatly deplored.

THE PROTECTION OF DRINKING-WATER SUPPLIES ON RAILWAYS.

THE extension of facilities for dining and sleeping on railway journeys has brought into increased importance the supply of pure water to restaurant and other cars. This matter is naturally of greater importance in America than it is with us owing to larger quantities of water drunk usually by the

American; and since the distances travelled are so great there is considerable probability that on any journey the supply will be renewed from several different sources, some of which may be of doubtful quality and many not under any sanitary control. The danger anticipated from this source has led to the appointment of a very strong commission by the American Treasury, which has fixed a bacteriological standard for the drinking-water supplied by common carriers in inter-state commerce.[1] The fixing of bacteriological standards of purity, or rather, as is pointed out by the commission, of permissible impurity, is more readily accepted in America than with us, as here we rely chiefly on sanitary control and inspection to attain the same ends. A very reasonable standard has been suggested and adopted, based on the number of organisms developing on agar at 37° C. in 24 hours, and on the absence of B. coli in at least four out of five 10 c.c. samples. Since the control or its enforcement rests ultimately on a legal basis it is satisfactory to find that the standard to be adopted, the methods to be employed in its determination, and the organism which for legal purposes is to be regarded as B. coli are all accurately defined. In these respects the report is instructive. In England there is no excuse for the use by any railway company of water from a polluted or uninspected source, and it is practically always drawn from a public water-supply. This does not, however, exclude danger from contamination during storage, and the publication of the report of the American commission may be of service in directing attention to this question of the purity of the water supplied by our railway companies.

A SUBJECT OF ARTIFICIAL PNEUMOTHORAX IN THE FIGHTING LINE.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Oct. 30th M. E. Rist showed a man the subject of artificial pneumothorax who had taken part in the war. The case was remarkable not only as evidence of the value of a method of treatment of pulmonary tuberculosis which has rapidly gained in favour in recent years, but of the spirit which animates our gallant allies. The patient was a man, aged 28 years, who was by occupation a translator. In September, 1913, tuberculosis suddenly manifested itself by repeated and profuse hæmoptysis, fever, nocturnal sweats, and a loss in weight of 5 to 6 kilogrammes in a few weeks. He was admitted into hospital under the care of M. Léon Bernard, who found that there was already a cavity in the upper lobe of the right lung. The disease was therefore of a severe and rapid type. In October pneumothorax was induced. The result was excellent; the fever and hæmoptysis disappeared and weight was gained. After six weeks the patient went to the country for three months. On his return he was able to resume his occupation provided he submitted to insufflation of nitrogen every fortnight. When war was declared he joined the infantry regiment to which he belonged, and came to hospital for a final insufflation. For the first time a little pleural effusion was found to accompany the pneumothorax. On August 4th he was at Quesnoy. On the 10th he marched to Avesnes, a distance of 15 kilometres, from which he went to Lille. On the 20th he marched 53 kilometres to Béthune, with a two hours' halt at La Bassée. Two days later he marched by night to Arras, a distance of 20 kilometres. On the 27th he marched to Doullens, a distance of 16 kilometres. He was then very fatigued. Nevertheless he was in the open air all night. On the 28th he was in the fighting line in contact with the enemy and fired 32 shots, but a rapid retreat exhausted him, and after 50 minutes he fell down and was taken to hospital. On Sept. 14th he returned to Paris, and after five days' rest was able to resume his work. On Oct. 15th he came to hospital, where the pneumothorax was found to be perfectly preserved at a pressure of 3 centimetres of water. This relatively elevated pressure was due to an increase of the effusion. Aspiration was performed, a litre and a half of citrine fluid was withdrawn, and nitrogen was insufflated. At the time of the report the patient was robust, had no fever, and neither coughed nor expectorated. It would seem from the evidence supplied by this case that artificial pneumothorax enabled a man who had been severely attacked with tuberculosis to engage in the campaign for a month under arduous conditions and to regain his health afterwards.

SYPHILIS THE UBIQUITOUS.

IN former days, while the path of the infective agent of syphilis, as well as the identity of that agent itself, was still matter for conjecture rather than certain knowledge, there was much temptation to make a pathological process which seemed so subterranean in its ways responsible for many of the lesions whose origin was shrouded in mystery. To-day the field available for such speculation has been encroached upon and limited from several directions. Many of the mysteries of pathology have been made plain, the probability or otherwise of a syphilitic factor has become a much more sharply assessible quantity, and specific tests for that factor have become available. Among these tests the Wassermann reaction has taken the chief place, and it is this that Dr. Leonard Findlay and Dr. Madge Robertson[1] have applied to certain diseases in which they suspected a luetic element. They employed the Glasgow technique devised by Browning and quote figures which lend strong support to their advocacy of this method. Even so, however, they do not claim that it is absolutely accurate, and constitutes a sharp dividing line between syphilis and not syphilis; they recognise a borderland of cases in which the test yields indeterminate results even when it is repeated several times. One of the lesions that have been examined from this point of view is eczema oris as seen in children. Thirty-three such cases have been tested serologically, and a positive reaction has been obtained in every one, either in the patient's own blood or in one of his near relatives. Again, 11 cases of congenital heart disease have been similarly tested, with almost the same result; in 7 of the children the serum reacted positively, while in 2 others that of one or other of the parents did so. In 33 cases of spastic diplegia the results were less decisive, but here there were 13 positive cases and 2 doubtful ones. Finally, a series of 22 mentally deficient and epileptic children included no less than 13 positive and 2 doubtful results. In neither of these two latter groups was it possible to discover any clinical difference between the syphilitic and the non-syphilitic cases. In estimating the importance of these findings it should not be forgotten that the presence of a positive Wassermann test in the serum of an individual does not necessarily prove that every symptom of disease from which that person is suffering is due to a lesion of syphilitic origin. The class of child whose parents are syphilitic is closely coincident with the class in which mental deficiency is likely to be rife, and it is possible that if there were a test available coincidences with other infections than syphilis might be worked out. Nevertheless the work of Dr. Findlay and Dr. Robertson is both stimulating and suggestive, and might with advantage be applied to other childhood diseases of obscure origin. It should be noted that in many of their positive cases the children presented no clinical stigmata of syphilis.

MEDICAL WOMEN FOR THE COMING SHORTAGE IN THE MEDICAL PROFESSION.

THE inevitable shortage of medical men which is resulting, and will for a considerable time continue to result, from the war affords matter for careful prevision. The great number of medical men who have already forsaken their civil sphere of activity for military service has already had its effect on hospital staffs, the various civil administrative medical staffs, and private practice. Moreover, there is little prospect that the toll will cease for some years to come. The wastage of war among those already engaged in military service will call for repeated drafts which also will become larger as the military medical establishment rises in numbers. The continuance of war will certainly withdraw a considerable number of young men from the medical, as from other, careers. With these considerations in view, the suggestion has been advanced in the *Times* by Dr. Mary Scharlieb that women of education and ability should turn their eyes to the medical profession, at least as an emergency measure, for, as she points out, women medical students need not of necessity be very young. Against the greater quickness of verbal memory and the superior plasticity of the very young Dr. Scharlieb insists that the trained mind, experience of life, and *savoir faire* of the more mature woman constitute an important set-off. The missionary field offers a special career for women also, while the fact that there are now several hospitals officered entirely by women in the theatre of war doing admittedly creditable and highly appreciated work amply demonstrates that there are many women at any rate who are quite equal to the strenuous demands of a medical career. Dr. Scharlieb's own experience of nearly 40 years justifies her in expressing the opinion that a medical career is capable of offering to a suitable woman candidate great happiness and satisfaction, combined with valuable opportunities for practical usefulness. We publish this week a letter signed by the President, Chairman, Dean, and Honorary Secretary of the London (Royal Free Hospital) School of Medicine for Women which coincides with Dr. Scharlieb's views, and forms a powerful appeal for the substantial endowment of an admirable institution. The school thoroughly deserves all the help that it seeks, alike for its past record and its future prospects.

WE regret to announce the sudden death of Professor A. van Gehuchten, professor of anatomy and neuropathology in the University of Louvain, which took place last week at Cambridge, where he was the guest of the University.

THE library and offices of the Royal Society of Medicine will be closed for the Christmas holidays from Thursday, Dec. 24th, to Monday, Dec. 28th, both days inclusive.

OWING to continued ill-health Dr. E. F. Bashford has been obliged to hand in to the executive committee his resignation of the post of General Superintendent of the Imperial Cancer Research Fund, and his resignation has been accepted.

THE TREATMENT OF WOUNDS IN WAR.

BY SIR ANTHONY A. BOWLBY, C.M.G.,
COLONEL, ARMY MEDICAL SERVICE; CONSULTING SURGEON TO THE EXPEDITIONARY FORCE.

General Headquarters, Expeditionary Force,
Nov. 30th, 1914.

WITH the Editor's permission I should like to join in the discussion opened by Sir Watson Cheyne at the recent meeting of the Medical Society on "The Treatment of Wounds in War,"[1] and I do so because for the last six weeks I have seen these wounds under different conditions from those in which they have been seen by the surgeons who took part in the debate. I spent my first three weeks in France at the base hospital at Rouen, but ever since the beginning of the "Battle of Ypres" I have been in daily attendance in one or other of the "clearing hospitals," or "clearing stations," as they are now to be called, to which the wounded are brought after being dressed in the field ambulances. They often arrive within a few hours of injury, but more frequently after a longer interval of 12 to 18 hours, and more rarely only after the lapse of one or two days. It must be remembered that in this war there is never an armistice for the burial of the dead or for the relief of the wounded, and it is usually only at night that our "stretcher-bearers" can remove men who cannot walk to the field ambulance. On the other hand, the motor ambulances cannot usually take the wounded on to the clearing hospitals by night because they would draw fire if they showed lights, and because the roads are almost impassable even by the light of day. The conditions of a field ambulance receiving many wounded at night quite preclude anything except the simplest dressings, or operations of urgency, and consequently nothing much is attempted before the day dawns. Soon after this the patients begin to be removed to the clearing hospitals. Men who are shot in our own attacks may lie outside our lines unaided even for days, for our own stretcher-bearers would be shot at once if they went out towards the German lines to help either British or German.

It must next be remembered that it has been the very worst cases—namely, the fractures of the femur and the leg bones, as well as the head and spine cases, and big shell wounds—which have been most delayed in getting to the field ambulances. For those men who were hit in the arms, or had slight flesh wounds, could get away with or without help in many instances, while these could not be moved without stretchers and bearers. And, in addition, again because they were so disabled, they have unavoidably been left lying in the wet mud of manured fields till their torn trousers and their wounds were so soaked in a mixture of blood and dirt that it was impossible even to get the torn muscles mechanically clean, let alone aseptic. In many cases also men have lost so much blood that they could not stand an operation on the chance of further loss by opening up wounds, and there is no doubt that their powers of resistance to microbic infection are in many cases greatly lowered by the combined effects of shock from the injury, from bleeding, and from exposure to cold and wet, with prolonged starvation. Such are the conditions in which many men are hit, and I will now turn to the nature of the wounds.

---

[1] THE LANCET, Nov. 21st, 1914, pp. 1185, 1200.

First, rifle bullet wounds. The wounds inflicted in this war differ most materially from those of the South African war in two essentials. In the first place, the bullet is a different one, and even at long range it hardly ever makes the very small punctures which the old Mauser bullet made. These small punctures were the indication of a correspondingly slight injury to the parts beneath, and so also the much larger wounds of exit and entrance of the new bullet indicate a correspondingly severe injury too. Both Mr. Makins and I are quite convinced that these bullet wounds are not comparable to the wounds of the Boer war, and I can further testify that the effects of our own bullet on the wounded Germans I have seen are also much more severe than were those of the Lee-Metford in 1900, though not so severe as the German missile. In the next place, it is well known that the Boers habitually fought at very long range, whereas here the exact contrary is the case. Most of the attacks on the British have been made at night, so that large masses of men could get close to the trenches before being seen, and instead of rifles being fired at from 800 to 1500 yards most of the rifle fire has been within 100 or 200 yards, while the great majority has been when the men were almost in contact or but few yards apart. The effect of this has been to cause the most typical "explosive effects," so that I have seen the greater part of the muscles of the forearm torn and extruded through a huge rent in the skin and fascia, and that without the bones being injured, in a case where a man was accidentally shot at a distance of three or four yards, and where there could be no possible doubt of the nature of the injury. Of course, in such cases where the bones are struck as well the effects are infinitely worse, and large portions of the muscles are rent and torn away with vessels and nerves, while parts of long bones are shot out and fractures extend over the whole length of the shaft. One might well believe that these injuries were due to shells, but I have had abundant evidence that these immense wounds have been caused in very large numbers when the men were so closely engaged in combat that all shell fire had ceased, and when there was consequently no doubt of their origin. Almost all the experiences of bullet wounds in the Boer war have been set at naught, and one never sees a clean hole bored through the patella as I saw six times in South Africa, or a bullet wound through the head whose entrance or exit was difficult to find. The bullet of the machine gun is the same as the rifle bullet.

Second, shell wounds. These of course are to be further divided into wounds by shrapnel bullets and wounds by fragments of the shell case. The effect of the shrapnel bullet varies in proportion to the height of the shell from the ground when it explodes and the velocity of the shell at the same moment. If a shell bursts when it has lost its velocity and is high in the air, the bullets also are quite spent and may fail to penetrate even the clothing. But if the shell bursts close to a man and when its velocity is very great, the bullets are projected with great force, and often many of them strike a single man. In this way whole limbs may be shattered or even torn off, and the viscera may be so injured that death is practically instantaneous. In intermediate cases the bullet penetrates with more or less velocity, and may in the latter case be deviated or stopped by a bone. These bullets are much more likely to carry into the wound portions of clothing than is the rifle bullet, and as their velocity and penetration are less they much more often lodge, otherwise they present no special points of interest. Portions of the shell case itself, or even the whole case, may strike a man, and the effect is the same as that caused by the howitzer shells.

A howitzer shell differs from shrapnel in that it contains no bullets, but only a bursting charge, and this charge usually is made to detonate when the shell strikes the ground. The wounds are therefore caused by the portions into which shell is shattered by the explosion, and while some of them may weigh several pounds, others may be smaller than a bullet. The wounds caused by these shells are the most horrible of all, and are much more often fatal than shrapnel wounds. The limb is often so violently contused by the mass of jagged metal tearing its way through all obstruction, that far beyond the actual wound the tissues are so injured that they slough in large masses. Immense rents are torn in the fascia and skin, and through these a mass of mangled muscles, fascia, and bone is thrust, much of which has its vessels so extensively destroyed that it is all dead from the moment of the injury. Such a wound presents a mass of slate-coloured or blackened tissue, from which blood-stained serum exudes, but which bleeds little. The whole limb in many cases is swollen by the extravasation of blood, which spreads far and wide along the intermuscular planes, and which by the tension it causes may yet further seriously interfere with the circulation of the limb as a whole. Large portions of clothing covered with mud are frequently thrust deep amongst the torn muscles, and gravel or soil may also be carried in by the shell.

Such, then, is a short description of the conditions in which the wounds are inflicted and the nature of the wounds themselves as seen soon after their infliction. I will now turn briefly to the question of the principles of treatment.

In the first place, it must be realised that the exigencies of war do not ordinarily permit of any equipment at clearing stations except that which can be easily removed at the shortest notice, and, as no tents or huts can be supplied, use has to be made of any available space or building. The accommodation will vary from a barn or a railway waiting-room to a town hall, or a church, or a school, or a college. But in the recent battle each clearing station had to divide its staff between several such places, as no one of them was large enough by itself. There may be no time whatever to prepare or clean such a building before the wounded begin to arrive, and there is seldom much time afterwards, while every wounded man and orderly adds to the mud on the floors. There are ordinarily no beds, and the patients lie on the stretchers on which they were carried in, but we have always obtained in the towns some beds for each of the "stations." The clearing station is equipped to provide for 200 cases. but it will be some indication of the pressure if it is realised that a single station has on several occasions dressed in 24 hours more than 1000 wounded.

It is seldom possible to remove all their blood- and mud-stained uniform from the soldiers because there is but little to take its place, and in fractures of the lower extremity most of the dressings and splints have to be applied and the wounds dressed as the patient lies on his stretcher raised on trestles or benches for the purpose. One room is set apart for operations and an operating table and accessories are set up here, and a well-trained orderly, or two if they can be spared, sees to the necessary sterilisation of bowls and instruments, &c.

There seems to be an idea that "aseptic" surgery has been practised at the front, but, as far as the clearing stations are concerned, this is entirely a misapprehension. I have myself never given up "antiseptic" principles and treatment, and I was glad to find that in every clearing hospital antiseptics were always used.

The usual routine for all flesh wounds which are of the punctured variety, and for all abdominal or thoracic wounds, is to paint the skin far around with 2 per cent. iodine in spirit, and to wash the wound itself with either carbolic acid 1 in 20 to 1 in 40; iodine from 1 to 2 drachms to the pint; or strong peroxide of hydrogen. The dressings have always been "antiseptic," and have always consisted of bicyanide of mercury gauze and absorbent wool, for "plain" gauze is considered to be unsuitable and is not provided. If there has been a fracture without extensive laceration or comminution the same procedure is adopted. But if there has been an extensive fracture, especially of the leg or thigh, with laceration, then, whenever it has been possible, the patient has been anæsthetised and the wounds have been enlarged and washed out with antiseptics, and broken bone has been removed and drainage provided.

But the number of cases in which such prolonged treatment can be carried out is necessarily limited by the space for work at disposal of the surgeons and the number of patients waiting treatment. For so much time may be spent on a very few patients that the net result would be harm to the majority. The remedy for all this is not merely a question of increasing the number of the surgeons. That has already been done. When one has to deal with such great numbers of wounded as were dealt with here it is largely a question of space and accommodation, and the difficulties encountered were far more due to the want of large enough suitable buildings near the battle than to anything else. It is easy to say that additional buildings might be obtained as they were required, or that the buildings we did occupy might have been improved. Both these things were done, but no sooner were we getting comfortable in the little town of "B" than the enemy's shells drove us out in a great hurry, and we had to seek other and safer buildings some miles away to our great disadvantage. The same thing happened at "Y," and here unfortunately with loss of life to both officers and orderlies of the Royal Army Medical Corps. In yet a third town we have had to move because of re-arrangement of the fighting line with the French. All these events of course show how impossible it is to try to pitch anything like a "general hospital" close to the front, and if our "clearing stations" had not been very portable we should have undoubtedly been obliged to leave them behind in the hands of the enemy. War is war, and the surgery of war is not the surgery of peace, and never will be. The total number of wounded in this prolonged battle has been very great and the actual figures I am now able to give will show at a glance what the work has been like. At one time the total number of wounded treated at the clearing stations was at the rate of more than 1200 a day, and on one day was over 3000. If these had been equally distributed amongst all the clearing stations on our 40 miles of front and had all come in as room was made for them these difficulties would have been less; but, as a fact, the pressure came especially on three or four stations, and the bulk of the wounded usually came in at the rate of many hundreds within two or three hours. The result was that often every square yard of floor space was taken up by hundreds of stretchers holding wounded men, and many who had injured hands and forearms were at first unable to get sitting space. Yet all these men were always fed and cared for and dressed during the day on which they were admitted. When one thinks that in a London hospital with ample space and permanent equipment the resident staff are really very busy if they have 20 broken legs to treat in a day, and that an operating surgeon who gets through six or eight operations in an afternoon, with plenty of assistants, has done a hard day's work, it is possible to get a faint idea of what it is to treat a hundred or more compound fractures besides caring for five or six hundred other men shot through the chest, the abdomen, the head, &c., and many of whom required immediate attention. And besides the difficulties due to the mere numbers and want of space it must always be kept in mind that the whole object of a clearing hospital is temporarily to treat the patients and send them as soon as possible to the base hospital, so as to make room and be ready for more hundreds of patients from the next day's fighting. To-day's wounded must all be treated to-day, and the work of filling ambulances and trains must follow as soon as possible on the treatment of the wounds, so that what with unloading ambulances as they arrive and reloading them and the hospital trains, many hours' hard work have to be done by the orderlies and surgeons, in addition to treating the wounds. Yet one clearing hospital by working day and night treated more than 1000 cases on each of three consecutive days.

The fact that so many wounds suppurate has caused criticism of the methods adopted, but if methods are judged solely by results without accurate knowledge of the conditions, then mistakes are liable to occur. My own opinion is that, even granted there were abundant time and opportunity in all the clearing stations, the most skilful treatment would not prevent nearly all the worst wounds from suppurating. As I have already pointed out, these are the very patients whose arrival is liable to be unavoidably delayed because they are so severely injured; and their wounds are contaminated before arrival, not by the "clean dirt" of the sun-dried veld, but by a highly septic and manured soil. In these severe wounds also there is often so much necrosing soft tissue that even a slight infection would be difficult to overcome, let alone a massive infection of a large area. Yet I fully agree that many of these severe wounds should be opened up under an anæsthetic if conditions are sufficiently favourable, and Dr. Rowlands and I have already advocated this in a report on dry gangrene[2] issued some weeks ago.

But it may fairly be pointed out that even if wounds have suppurated there has been an almost complete absence in the base hospitals, as well as those in the front, of real pyæmia, and there have, of course, been no cases of true "hospital gangrene" anywhere. My own opinion is that the wounded as a whole have done very well indeed considering that the buildings were necessarily quite unprepared for surgical work when the battle began, that the men and their clothes were very dirty, that it was often impossible to bring in the wounded for many hours, that the wounds were commonly grossly contaminated before they could be treated, and, above all, that the injured parts were often quite devitalised by the violence to which they had been submitted.

I confess that I have nothing but admiration for the way in which difficulties have been overcome, and I am also convinced that the percentage of mortality amongst the wounded has been very low. But all the same I hope and think that all who have worked here have learned, and are learning, to improve their methods, so that if in the near future there are yet more wounded men, these may benefit by past experience as well as by the criticism and advice of our colleagues.

OUR ARMY'S TEETH.

By F. NEWLAND-PEDLEY, F.R.C.S. ENG., L.D.S.,
CONSULTING DENTAL SURGEON TO GUY'S HOSPITAL.

British Red Cross Hospital No. 2, Rouen, Dec. 12th.

THE arrival of the first dental officers for service with the troops in France was welcome, for they were very much needed. A great deal of improvement has been effected in the teeth of the army since the Boer War, and the authorities are now very anxious to do everything possible for the care of the teeth, but the question is, How is it to be done? An ideal way would be to mobilise the dental surgeons, making the unregistered men and mechanics act as assistants to the dental surgeons. In this way we could repair the teeth of the army even in the battlefield.

Another way would be carefully to inspect and treat the teeth of every child from the time the first tooth is cut, making dental neglect a punishable offence. This would give admirable results in 25 years, and we might expect additional benefits by heredity, but our needs in this war are immediate, for we want as many men as we can get and they are no use without teeth. Artificial teeth do not always yield good results and offer too great a chance to the malingerer. In a moment he may pocket his artificial teeth or get rid of them, and then be sent home amongst the dental failures. So the only thing to do is to take as many likely men as we can get, even if their teeth are a little below standard, remembering that in exceptional cases even an edentulous man may not suffer from indigestion. I once made a complete set of teeth for a ship's captain, and he always wore them excepting at meals when he removed them, as he had become accustomed to take his food, including biscuit, without teeth, and his digestion was quite satisfactory. This case is abnormal, and I only quote it to show that no rigid line can be drawn, and we can take some doubtful cases if we are prepared to send out a good corps of dental surgeons to do as much work as possible. But this dental corps must not be satisfied to take out teeth, but should be prepared to do a good day's work saving them. They should be organised, inspected, and should work under their own officers. The extractions do not take long and all available time should be devoted to treating exposed pulps and filling carious teeth. In this way a large number of men who otherwise would be lost can be patched up till their return at the end of the war when the dental departments can attend to them.

Reverting to the matter of artificial teeth, there is a wise provision of the authorities that sergeants and some others shall have a right to artificial teeth. The services of the local practitioners may be utilised for a certain number of these cases, saving their voyage home. When there are many wounded it is a great advantage to have "gas," for when men are weak they dread the dentist more than they feared a "Jack Johnson" when they were well. I applied for "gas" on these grounds, and it was sent out to me at once. My experiences at Deelfontein during the Boer war, and now at Rouen, are the basis on which I frame these suggestions. I came to Rouen as a volunteer dental surgeon nearly two months ago, and for the first six weeks I received cases from all quarters, Red Cross and general hospitals and convalescent camp included. If the Government is prepared to send out enough dental officers a large number of soldiers can be saved to the army, but they must come prepared to do the usual full day's work.

MEDICINE AND THE LAW.

A Judge on Professional Secrecy.

IN his charge to the grand jury in the case of Annie Hodgkiss, at the Birmingham Autumn Assizes, on Dec. 1st, Mr. Justice Avory made the following observations:—

> This woman has been committed on the coroner's inquisition on a charge of murder. The magistrates who have investigated the case have dismissed the charge. The deceased woman, according to the evidence, clearly died as the result of an illegal operation. Three medical men in succession attended her, and to one at least she confided the name of the person who performed the act. No information was given to the police or the authorities, and the woman died without any deposition being taken or without any statement being made by her on her death bed which could be used in a court of law. With the exception of a letter, which was found among deceased's papers, apparently making an appointment with the accused woman, there is absolutely no evidence against this accused person of having performed any operation upon the deceased woman, and the magistrates. taking that view, dismissed the charge. I need not remind you that any statement made by the deceased woman to a medical man is not evidence in a court of law. I can see no evidence, as the case now stands, which will justify you in finding a true bill against the prisoner for murder. The law provides that in the case of any person who is seriously ill, and who, in the opinion of a medical man, is not likely to recover, the evidence of such a person may be taken by a justice of the peace. Under circumstances like those in the present case, I cannot doubt

---

[2] THE LANCET, Nov. 28th, 1914, p. 1265.

> that it is the duty of the medical man to communicate with the police or with the authorities in order that one or other of those steps may be taken for the purpose of assisting in the administration of justice. No one would wish to see disturbed the confidential relation which exists, and which must exist, between the medical man and his patient in order that the medical man may properly discharge his duty towards his patient; but there are cases, of which it appears to me that this was one, where the desire to preserve that confidence must be subordinated to the duty which is cast upon every good citizen to assist in the investigation of a serious crime such as is here imputed to this woman. In consequence of no information having been given it appears to me that there is no evidence whatever upon which this woman can properly be put upon her trial. I have been moved to make these observations because it has been brought to my notice that an opinion, to which I was a party some 20 years ago, when I was at the Bar, has been either misunderstood or misrepresented in a text-book of medical ethics, and I am anxious to remove any such misunderstanding if it exists. It may be the moral duty of the medical man, even in cases where the patient is not dying, or not unlikely to recover, to communicate with the authorities when he sees good reason to believe that a criminal offence has been committed. However that may be, I cannot doubt that in such a case as the present, where the woman was, in the opinion of the medical man, likely to die, and, therefore, her evidence was likely to be lost, it was his duty, and that some one of those gentlemen ought to have done it in this case.

We doubt if there will be any general agreement in the medical profession with Mr. Justice Avory's views.

A Panel Doctor's Fees Attached.

In the case of O'Driscoll *v.* Manchester Insurance Committee in the High Court of Justice, Mr. Justice Rowlatt, sitting without a jury, recently delivered an important judgment upon the question whether a panel doctor's fees can be attached. The executors of Dr. O'Driscoll, a deceased medical man, formerly in practice at Manchester, sold the goodwill of his practice to Mr. W. D. Sweeny, who was unable to pay the whole of the agreed purchase money, and against whom judgment was obtained for the balance due. In order to satisfy this judgment the plaintiffs obtained a conditional order attaching all moneys due from the committee to Mr. Sweeny as a member of the panel. Mr. Justice Rowlatt distinguished between the case of payments due to a member of the panel and the salaries of officers of the Crown, which are not liable to attachment, and held that as soon as moneys came into the hands of the Insurance Committee for distribution among the members of the panel a debt became due to every medical man who had done work under contract with the committee, and that the money thus becoming due was liable to attachment.

Action for Negligence in South Africa.

The Supreme Court of South Africa recently heard the appeal of Mr. John Mitchell against whom a jury had found a verdict for £100 damages on the ground of alleged negligence in performing an operation whereby a steel needle used with a Potain aspirator had been broken and remained in the patient's body. In allowing the appeal and giving judgment for the appellant, Mr. Mitchell, Sir James Rose-Innes, who presided, dwelt upon the necessity for proving, on behalf of a plaintiff in such a case, that the defendant did not employ reasonable care and skill, not that he did not bring to bear the highest possible degree of professional skill; also that a mistaken diagnosis, if proved, which had not been done, or the mere fact of an accident taking place, did not constitute proof of negligence. The appeal succeeded because the court was of the opinion that there was not sufficient evidence to justify reasonable men in finding that there was negligence. A feature in the case which received attention in the judgment delivered was that three specific questions were put to the jury at the trial: Was the defendant negligent? Did he negligently use an improper instrument? Was it the result of such negligence that the needle broke off and remained in the patient's body? The judge, however, at the same time told the jury that they were not bound to answer these questions, but might give a general verdict. They adopted the latter course, and Sir James Rose-Innes, very reasonably, treated this as meaning that they could not make up their minds as to any definite negligence upon which damages could be based, but desired to compensate the plaintiff for having a needle in his back.

Easy Purchase of Poisonous Drugs.

Dr. F. J. Waldo had occasion to explain at length to a jury recently in the City coroner's court the dangers of indulgence in cocaine and morphine, and to comment upon the ease with which they can be purchased from druggists who are willing to evade the formalities imposed by the Pharmacy Act. In the case before him the deceased, an Indian woman from Assam, had been living with a retired civil engineer for many years, and both were addicted to injecting morphine and cocaine. The man, who admitted having seen the deceased take 10 grains of cocaine in one day, had gone out and purchased a supply from a druggist in Holborn, without having to sign in any book kept for the purpose, and had returned to find his companion unconscious. The deceased had died at St. Bartholomew's Hospital from heart failure resulting from cocaine and morphine poisoning, and as there were bottles produced, which had apparently been purchased by the man or woman, containing the drugs but not bearing the labels prescribed by the law, Dr. Waldo suggested that the police should make inquiry and if possible take action against the vendors.

A Pernicious Impostor.

At the recent sessions of the Central Criminal Court sentence of three years' penal servitude was passed upon John Cubbin, who pleaded guilty to charges of giving certificates of the cause of death, not being a medical practitioner, and of committing perjury at inquests where he swore that he was qualified. His record was an unusually bad one. He had been fined in connexion with the giving of certificates and use of medical titles in 1900, and on subsequent occasions had been convicted of theft and of bigamy. He had been sentenced to five years' penal servitude in 1905, and had in 1913 been released from prison as a convict on licence, soon after which he had procured engagements first from one medical practitioner and then from another as an assistant. In the last instance, when he was using the name of Harrison and posing as a surgeon-general, he claimed to have succeeded to a baronetcy through the death of an imaginary relative. Medical men engaging assistants and locum-tenents should take the case of Cubbin as a warning. Proper inquiries are absolutely necessary in the absence of an introduction of a trustworthy character, and the Medical Register should also be consulted.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Dec. 10th, Sir W. WATSON CHEYNE, the President, being in the chair.

The PRESIDENT reported that Sir Berkeley Moynihan had left England to take up his duties as a consulting surgeon to H.M. forces overseas; and it was resolved to grant leave of absence from the meetings of the Council to him for the period of his service abroad.

A report was read from the Board of Examiners in anatomy and physiology for the Fellowship stating that at the recent examination 57 candidates were examined, of whom 15 were approved and 42 rejected.

It was resolved to grant Diplomas of Fellowship to nine successful candidates.

In accordance with a report from the Board of Examiners in Dental Surgery it was resolved to grant the Licence in Dental Surgery to 35 successful candidates.

Examiners were appointed to the various examinations, the only new examiner being Dr. C. M. Hinds Howell, who was appointed examiner in physiology for the Second Conjoint Examination.

Mr. H. F. Waterhouse was re-elected a member of the Court of Examiners.

A report was received from the committee on the annual report of the Council dealing with the recent annual meeting, and in accordance with that report it was resolved that—

> As the matter referred to in the resolution carried at the annual meeting of the Fellows and Members was very fully considered by the Council so recently as March of this year, the Council see no advantage in reopening the discussion at the present time.

In accordance with the report of the committee of management, it was resolved to add the Newcastle-on-Tyne Royal Grammar School to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

A letter was read from the Professional Classes War Relief Council stating that it has been formed to deal with distress in the professional classes directly due to the war, and that it was decided at the last meeting of the council to ask the College to nominate a representative to serve on the council. The President was nominated.

A letter was read from Sir Henry Morris reporting the proceedings of the General Medical Council at their recent session. The letter was received and entered on the minutes, and the best thanks of the Council were given to Sir Henry Morris for his services as the representative of the College on the General Medical Council.

The PRESIDENT announced that he would deliver the Hunterian Oration on Monday, Feb. 15th, 1915, and it was resolved that there should be no Hunterian dinner.

A letter was read from Mr. F. G. Parsons stating that at the annual general meeting of the licensed teachers of anatomy in London, held on Nov. 26th, it was decided to ask the Council of the Royal College of Surgeons to help in taking further measures with a view to increasing the present inadequate supply of "subjects" for dissection, and to suggest a conference between representatives of the Council and the licensed teachers. A committee of the Council was appointed to meet the teachers.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted commissions as Surgeons for temporary service in His Majesty's Fleet:—Dated Dec. 5th: James Robertson Adam. Dated Dec. 7th: Ernest Farrant Cox, Frank Elliott, Edward Heffernan, William Archibald Mills, William John Morris, John Morrison, Horace Clulow Nixon, George Marshall Oakden, Augustus Kevin Roche, and Andrew Edgar Struthers.

Temporary Surgeon: A. P. Barrett to the *Newmarket* and for duty in Clacton.

ROYAL NAVAL VOLUNTEER RESERVE.

The following have been entered as Surgeon Probationers for temporary service:—C. McDonald, G. A. Paris, N. K. Henderson, W. O. Lodge, C. T. Helsham, W. W. K. Brown, W. O'G. Donoghue, P. G. S. Davis, K. M. Ross, W. J. McB. Ross, W. A. Turner, N. A. H. Turner, J. F. Smith, D. S. Prentice, and P. H. S. Smith.

ROYAL ARMY MEDICAL CORPS.

The undermentioned to be temporary Lieutenant-Colonels:—Dated Nov. 12th: Major Arthur E. J. Barker, 3rd London General Hospital, Territorial Force. Dated Nov. 21st: Sir Thomas Myles. Dated Nov. 22nd: Sir Charles Bent Ball, Bart., and Captain Sir William A. Lane, Bart., 2nd London (City of London) General Hospital, Territorial Force. Dated Dec. 1st: Major Sir Frederic S. Eve, 2nd London (City of London) General Hospital, Territorial Force, and Major James Swain, 2nd Southern General Hospital, Territorial Force. Dated Dec. 3rd: Major William Aldren Turner, 4th London General Hospital, Territorial Force.

The undermentioned to be temporary Lieutenants:—Dated Nov. 23rd, 1914: Keith Douglas Falconer, William Aloysius Murphy, Lawrence Weir Bain, Basil Cedric Ashton, Walter de Marchot Hill, and James MacGregor. Dated Nov. 24th: John Charles Venniker, Cunison Deans Rankin, Ronald Wingrave Duncan, Charles Jerome Alexander Nicolai Mercier, Crawford Lundie, Thomas Perrin, and Alexander Galletly. Dated Nov. 26th: Arthur Davies and John Spencer-Daniell. Dated Nov. 28th: William Hector Wotton. Dated Nov. 29th: Edwin FitzGerald O'Connor. Dated Nov. 30th: Lewis Hay Irving Bell, Holden Carson, Robert Joseph English, and Charles James Morton. Dated Dec. 1st: Joseph Elias Barnes, William Herbert Neil, Harold Dunkerley, Harold Francis Golding Noyes, Bartholomew Joseph Mullin, Ricardo Cope, Ralph Martin Soames, William Annandale Troup, Claude Harry Mills, Meredith Ffoulkes, John Neville Griffiths, Charles Howden Harbinson, John Francis O'Malley, John Harold Wilson, Robert Waller Willcocks, Arthur Norman Leeming, Neil Islay Sinclair, Walter Stuart Evans, Henry Michael Joseph, Tobias Rustat Hemsted Blake, Oscar Phillip Napier Pearn, John Arthur Noel Scott, John Finlayson McGill Sloan, and David Roberts Williams.

Lieutenant Edward A. Seagar relinquishes his temporary commission (dated Dec. 7th, 1914).

SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Henry S. A. Alexander, Arthur L. Anthony, John Deighton, Gerald C. Dixon, Hugh A. Fawcett, Cromwell Gamble, Herbert L. Garson, Gilbert A. Harvey, James R. C. Mackintosh, Mathew McKnight, Wilfrid W. Phillips, William K. Russell, Bertrand C. O. Sheridan, John S. Sloper, Harry N. Stafford, Robert I. Sullivan, Charles G. Waddington, John R. N. Warburton, George W. Watson, Colin Wilson, and William A. Young.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Robert Alfred Greenwood to be Captain.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd South Midland Field Ambulance: Frank Treadwell Boucher to be Lieutenant.

2nd Wessex Field Ambulance: Major Harry Compton Parsons, Reserve of Officers, New Zealand Medical Corps, to be Major (temporary). To be Captains (temporary): Gerald Dudley Freer, Leonard Leighton Hanham (late Captain, A.M.R.), and Harold Cotterell Adams. To be Lieutenants: William Thomas Pearse Meade-King, Henry Nunan Collier, and Charles Fenwick Backhouse.

3rd Wessex Field Ambulance: To be Lieutenants: Arthur Holdsworth Davis, Frederick Tooth, Frederick William Brunker, Philip McRitchie, Frank Lindsay Dickson, and Frederick Hardie.

1st London (City of London) General Hospital: Majors to be Lieutenant-Colonels: Archibald E. Garrod and Holburt J. Waring. Captains to be Majors: Percival Horton-Smith Hartley, C.V.O., and George E. Gask.

3rd London General Hospital: The undermentioned Lieutenants are seconded: George H. D. Webb and Edward Smeed.

4th London General Hospital: Major William A. Turner is seconded.

East Anglian Clearing Hospital: Lieutenant William Redpath to be Captain.

1st Highland Field Ambulance: Captain James Robertson to be Major (temporary). Bernard Gordon Beveridge to be Lieutenant.

3rd Highland Field Ambulance: Captain George Waterston Miller to be Major.

1st Welsh Field Ambulance: Captain Thomas Donovan to be Major.

2nd Welsh Field Ambulance: Captain Owen L. Rhys to be Lieutenant-Colonel (temporary). Barry Keyte Tenison Collins to be Lieutenant.

3rd Welsh Field Ambulance: Captain Daniel E. Evans to be Lieutenant-Colonel (temporary). The undermentioned to be Lieutenants: Richard James Isaac, Harry MacManus Soden, Joseph Carroll, and John Joseph Porter.

2nd Western General Hospital: Alfred Ernest Barclay to be Captain.

South Midland Clearing Hospital: Captains Charles B. Baxter and James L. Joyce, from Attached to Units other than Medical Units, to be Captains. Henry Gauntlett Langdale Smith to be Lieutenant.

London Mounted Brigade Field Ambulance: Captain James W. McIntosh to be Major (temporary). Lieutenant William F. Smartt to be Captain (temporary).

1st Home Counties Field Ambulance: Captain Arthur T. Falwasser to be Major (temporary).

1st London (City of London) Field Ambulance: Lieutenant David J. Scott and Lieutenant Archibald Leitch to be Captains (temporary).

3rd London (City of London) Field Ambulance: Major John A. Masters, from Attached to Units other than Medical Units, to be Lieutenant-Colonel (temporary). Captain George L. L. Lawson to be Major (temporary). Captain Myer Coplans is seconded. Lieutenant Robert Carswell to be Captain (temporary).

4th London Field Ambulance: Captain Thomas B. Layton to be Major (temporary). John Mackay Plews to be Lieutenant.

5th London Field Ambulance: The undermentioned Lieutenants to be Captains (temporary): John E. Sandilands and George Scott.

1st Northumbrian Field Ambulance: John Hamilton Barclay to be Lieutenant.

1st West Riding Field Ambulance: Lawrence Abel Mackenzie to be Lieutenant.

1st Western General Hospital: Ralph Lamb to be Lieutenant.

Northumbrian Clearing Hospital: John Stanley Manford (late Captain, 3rd Volunteer Battalion, The Northumberland Fusiliers) to be Captain. Richard Woodward Swayne to be Lieutenant.

1st East Anglian Field Ambulance: Arthur William Paterson to be Lieutenant.

2nd Eastern General Hospital: William Barrington Prowse to be Captain available for service on mobilisation.

1st North Midland Field Ambulance: Charles Brand Johnstone to be Lieutenant.

2nd North Midland Field Ambulance: Edward Crawford Trench Emerson to be Lieutenant.

2nd Northern General Hospital: Lieutenant George P. Anning, from Attached to Units other than Medical Units, to be Captain.

4th Northern General Hospital: Douglas Edward Darbyshire to be Captain.

2nd London Sanitary Company: Captain Charles M. Fegen to be Major (temporary). Lieutenant Frederick G. Caley to be Captain (temporary).

2nd London Clearing Hospital: Iorwerth Hubert Lloyd-Williams to be Lieutenant.

1st Wessex Field Ambulance: To be Lieutenants: Edmond Langley Meynell, Fred Ellis, Claude John Eddowes Bennett, and John Arthur Bell. Lieutenant Charles H. Maskew, from the 3rd Wessex Field Ambulance, to be Lieutenant.

Attached to Units other than Medical Units.—Major Thomas H. Chittenden, from the London Mounted Brigade Field Ambulance, to be Major. To be Captains: Lieutenant Robert Proudfoot and Bertram Maughan Footner (late Lieutenant, 5th Battalion, The South Staffordshire Regiment). To be Lieutenants: Lieutenant Leonard B. Baird (from 3rd West Lancashire Field Ambulance), Lieutenant Harold D. Lane (from the 3rd North Midland Field Ambulance), Thomas Louis de Courcy, Charles Gerald Tench, Louis Bruce Stringer, Ernest Edward Balman Landon, Lieutenant Herbert W. Joyce (from 1st North Midland Field Ambulance), John Carrington Marklove, and George Hooper Rains.

TERRITORIAL FORCE RESERVE.

Captains from the 1st Northern General Hospital to be Captains: Joseph C. Stewart and James W. Heslop.

DEATHS IN THE SERVICES.

Deputy Surgeon-General William Henry Harris, late I.M.S., at Shanklin, in his eighty-fifth year. He joined the Madras Medical Service in 1853 and attained the rank of deputy surgeon-general in 1881. He was formerly superintendent of the Lying-in Hospital and professor of midwifery in University College, Madras.

THE HEALTH OF THE NAVY.

The statistical report on the Health of the Navy for the year 1913 has just been issued by the Admiralty.[1] It is signed by the Medical Director-General, Sir Arthur May, K.C.B., and dated Oct. 14th, 1914. The brief introduction points out that in the present report the appendix, which formerly contained articles on professional subjects by medical officers in the Royal Navy, has been omitted owing to the intended publication of a quarterly naval medical journal. Owing to the general mobilisation of the Navy on August 1st, 1914, the remarks on the various returns, which were in course of compilation at that date, have been condensed as far as possible. Once again the Medical Director-General is able to report that the returns for the total force for the year under review show a continuous improvement in the general health of the Fleet as compared with the preceding five years. The total force, corrected for time, in the year 1913 was 126,830, and the total number of cases of disease and injury entered on the sick list was 77,438, giving a ratio of 610·56 per 1000, a decrease of 46·09 as compared with the average ratio for the preceding five years. The total number of cases of venereal disease recorded was 11,821, giving a satisfactory decrease of 22·85 per 1000 in the case ratio as compared with the average for the previous half decade. Five wounds in action were recorded, with one death. How different will the figures for 1914 look in this respect!

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

For obvious reasons the war must have seriously affected military journalism, and this probably accounts for the fact that the October issue of the Journal of the Royal Army Medical Corps has only reached us on the eve of going to press this week. It contains several interesting and topical articles, among others being Some Essential Factors in the Construction of Field Service and Expeditionary Rations, by Lieutenant-Colonel W. W. O. Beveridge, D.S.O.; Carbon Dioxide Snow with Special Reference to the Treatment of Oriental Cores, by Captain T. J. Mitchell; An Improved Method of Carrying a Wounded Man by a Single Bearer, by Captain D. B. McGrigor; A Modified System of Accounting for Medical and Surgical Supplies in Military Hospitals, and Army Biscuit Receipts.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8149 births and 5442 deaths were registered during the week ended Saturday, Dec. 12th. The annual rate of mortality in these towns, which had been 14·3, 16·6, and 15·3 per 1000 in the three preceding weeks, rose in the week under notice to 15·7 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 14·3, against 14·6 per 1000 in the metropolis. Among the several towns the death-rate last week ranged from 5·7 in Ilford, 6·1 in Darlington, 6·6 in Eastbourne, 6·8 in Aberdare, and 6·9 in Carlisle to 21·2 in York, 21·5 in Southampton, 21·9 in Hastings, 23·9 in Newcastle-on-Tyne, and 24·5 in Wigan.

The 5442 deaths from all causes were 113 in excess of the number in the previous week, and included 429 which were referred to the principal epidemic diseases, against 448 and 439 in the two preceding weeks. Of these 429 deaths, 181 resulted from measles, 71 from infantile diarrhœal diseases, 62 from diphtheria, 50 from whooping-cough, 48 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·2, against 1·3 per 1000 in each of the four preceding weeks. The deaths attributed to measles, which had been 148, 174, and 155 in the three preceding weeks, rose to 181 last week, and caused the highest annual death-rates of 1·4 in Plymouth and in Huddersfield, 1·7 in Liverpool, 1·9 in Birkenhead, 2·6 in Gateshead, 3·2 in Rotherham, 4·6 in Wigan, and 4·8 in Newcastle-on-Tyne. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 138, 102, and 94 in the three preceding weeks, further declined to 71 last week, and included 15 in London, and 5 each in Birmingham and Liverpool. The fatal cases of diphtheria, which had increased from 58 to 99 in the four preceding weeks, fell to 62 last week, and included 13 in London, 7 in Birmingham, 5 in Liverpool, and 3 each in Tottenham, Northampton, and Hull. The deaths attributed to whooping-cough, which had been 35, 42, and 48 in the three preceding weeks, further rose to 50 last week, of which 10 were registered in London, 5 in Bristol, 4 in Newcastle-on-Tyne, and 2 each in Portsmouth, Stoke-on-Trent, and Rhondda. The deaths referred to scarlet fever, which had been 28, 42, and 30 in the three preceding weeks, rose to 48 last week, which was the highest number recorded in any week of the current year, and included 11 in London, 5 in Sheffield, 4 in Liverpool, and 3 each in Birmingham, Manchester, and

---

[1] Cd. 7683. Price 7½*d*. Wyman and Sons, Limited, Fetter-lane, E.C.

Preston. The fatal cases of enteric fever, which had been 17. 11, and 13 in the three preceding weeks, further rose to 17 last week, and included 2 each in London, Liverpool, Halifax, Bradford, and Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 5005, 5035, and 4980 at the end of the three preceding weeks, had further fallen to 4893 on Saturday last; 504 new cases were admitted during the week, against 627, 623, and 537 in the three preceding weeks. These hospitals also contained on Saturday last 1624 cases of diphtheria, 59 of enteric fever, 50 of measles, and 46 of whooping-cough, but not one of small-pox. The 1340 deaths from all causes in London were 15 in excess of the number in the previous week, and corresponded to an annual death-rate of 15·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 203, 324, and 312 in the three preceding weeks, rose to 317 last week, and were 90 above the number recorded in the corresponding week of last year.

Of the 5442 deaths from all causes in the 97 towns, 206 resulted from different forms of violence and 456 were the subject of coroners' inquests, while 1485 occurred in public institutions. The causes of 47, or 0·9 per cent., were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Nottingham, and in 70 other smaller towns. Of the 47 uncertified causes of death, 12 were registered in Birmingham, 8 in Liverpool, 4 in Southampton, 3 in Gateshead, and 2 each in Manchester and Preston.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1163 births and 780 deaths were registered during the week ended Saturday, Dec. 12th. The annual rate of mortality in these towns, which had been 16·6, 18·4, and 18·3 per 1000 in the three preceding weeks, further declined to 17·7 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 16·2, against 14·3 per 1000 in the 97 large English towns. Among the several towns the death-rate ranged from 11·7 in Clydebank, 13·5 in Edinburgh, and 15·3 in Perth, to 20·4 in Falkirk, 20·5 in Ayr, and 23·5 in Kilmarnock.

The 780 deaths from all causes were 23 fewer than the number in the previous week, and included 76 which were referred to the principal epidemic diseases, against 82 and 79 in the two preceding weeks. Of these 76 deaths, 32 resulted from whooping-cough, 16 from diphtheria, 14 from scarlet fever, 8 from infantile diarrhœal diseases, 4 from enteric fever, and 2 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·7, against 1·2 per 1000 in the 97 large English towns. The deaths attributed to whooping-cough, which had increased from 7 to 30 in the four preceding weeks, further rose to 32 last week, of which 24 occurred in Glasgow and 2 each in Dundee and Motherwell. The deaths referred to diphtheria, which had been 17, 13, and 20 in the three preceding weeks, fell to 16 last week, and included 5 in Glasgow, 4 in Aberdeen, and 3 in Edinburgh. The fatal cases of scarlet fever, which had been 16, 25, and 15 in the three preceding weeks, were 14 last week, and included 9 in Glasgow. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had declined from 31 to 10 in the seven preceding weeks, further fell to 8 last week, of which 3 belonged to Glasgow and 2 to Dundee. The 4 deaths referred to enteric fever, of which 2 occurred in Edinburgh, were equal to the average in the earlier weeks of the quarter. The 2 fatal cases of measles were registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had steadily increased from 62 to 163 in the 12 preceding weeks, fell to 154 in the week under notice; 23 deaths resulted from different forms of violence, against 39 and 34 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 585 births and 488 deaths were registered during the week ended Saturday, Dec. 12th. The annual rate of mortality in these towns, which had increased from 17·7 to 20·1 per 1000 in the four preceding weeks, further rose to 21·1 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 17·7, against corresponding rates of 14·3 and 16·2 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 23·2 in Dublin (against 15·5 in London and 18·5 in Glasgow), 20·8 in Belfast, 25·2 in Cork, 17·8 in Londonderry, 19·0 in Limerick, and 30·4 in Waterford, while in the 21 smaller towns the mean death-rate was 16·1 per 1000.

The 488 deaths from all causes were 24 in excess of the number in the previous week, and included 43 which were referred to the principal epidemic diseases, against 40 and 42 in the two preceding weeks. Of these 43 deaths, 17 resulted from infantile diarrhœal diseases, 12 from measles, 8 from scarlet fever, 3 from whooping-cough, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·9, against corresponding rates of 1·2 and 1·7 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) atributed to diarrhœa and enteritis, which had been 13, 10, and 12 in the three preceding weeks, further rose to 17 last week, and included 9 in Dublin, 5 in Belfast, and 2 in Cork. The deaths referred to measles, which had been 10, 14, and 8 in the three preceding weeks, rose to 12 last week, and comprised 11 in Belfast and 1 in Cork. The fatal cases of scarlet fever, which had declined from 14 to 8 in the four preceding weeks, were again 8 last week, of which 3 were recorded in Belfast and 3 in Waterford. The 3 deaths attributed to whooping-cough, comprising 2 in Dublin and 1 in Belfast, were slightly below the average in the earlier weeks of the quarter. The fatal cases of diphtheria were registered in Dublin and Belfast, and that of enteric fever in Waterford. In addition to the above, a death from typhus occurred in Belfast and another in Cork.

The deaths referred to diseases of the respiratory system, which had been 85, 100, and 90 in the three preceding weeks, rose to 120 in the week under notice. Of the 488 deaths from all causes, 153, or 31 per cent., occurred in public institutions, and 8 resulted from various forms of violence. The causes of 16, or 3·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion did not exceed 0·9 per cent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A School for Injured Soldiers.

THE Mayor of Lyons intends to ask the support of the Government for a scheme he has brought forward on behalf of mutilated soldiers the nature of whose injuries renders their return to their former occupation impracticable. He suggests the creation of a school of instruction whereby such soldiers may be taught free of charge, while receiving the necessary medical and other care, some occupation for which they may be individually fitted, so as to enable them to maintain themselves.

A Rest Canteen at the Gare du Nord.

The English Red Cross has opened a rest canteen in the basement of the Gare du Nord, Paris, containing beds and well-installed lavatories. Tea, coffee, milk, roast beef, sandwiches, and sweets may be obtained there.

Entertainments for Wounded Soldiers.

The custom is spreading of enlivening the tedium for the wounded in hospital by good music and readings. Recitations and concerts have been organised by a member of the Comédie Française at the Fondation Thier, now a Red Cross hospital, and at the Hôpital Pitié, and a concert is being organised for the hospital at the Grand Palais. On Dec. 5th, in Professor Pozzi's service at the Hôpital Broca, an entertainment was given in the wards for those severely wounded, at which Professor Pozzi with all his staff assisted. Convalescents were present on deck chairs, wearing their uniform again for the first time.

Antityphoid Vaccination in Paris.

Antityphoid vaccination has been compulsory throughout the French Army since March. In October the Prefect of the Seine publicly announced that young men of the class of 1915 could be vaccinated before joining their corps, in which case they would only have to present their tickets to the medical authorities. A double object is thus

ttained : first, a relaxation of the strain on
ıe Military Medical Service; and secondly, the
ımiliarisation of the general public with anti-
yphoid vaccination. A special free medical service
nder the direction of Dr. Maurange, and approved
y the military authorities of Paris, has been estab-
shed in large offices by the generosity of the
larquis de Vogüé, President of the Society of St.
obain. Four boards sit there at the same time,
ach consisting of a vaccinating surgeon and his
ssistant, with a woman secretary. Everyone to
e vaccinated hands his ticket to the secretary,
ho indicates on it to the medical man whether it
a case for a first, second, or third injection.
fter an application of tincture of iodine the vac-
nated person goes away with his ticket and a
ıchet of aspirin. Professor Vincent's method and
accine are used. On one day alone this sanitary
rvice vaccinated 4100 recruits of the class of 1915,
ıd also 500 civilians, men, women, and children.
he organisation can vaccinate from 600 to 800
ersons at a sitting. With the thorough technique
nployed few or no serious reactions have been
oted. A few subjects have complained of a slight
eariness in the arm or a passing headache;
ver is still more rare, hardly 1 or 2 per cent.
he results of antityphoid vaccination are no
nger open to discussion. Not a single case of
orbidity or a death has been observed among the
ccinated since its introduction. The vaccination
the class of 1916 is already under consideration,
e service being prepared to vaccinate every
cruit, to whose advantage it is to have it done
advance of joining his corps. When once anti-
phoid vaccination shall have become usual, the
ourge of typhoid will greatly diminish.
Dec. 12th.

Correspondence.

"Audi alteram partem."

THE MEDICAL STUDENT'S DUTY.

To the Editor of THE LANCET.

SIR,—In my presidential address to the General
edical Council on Nov. 24th I expressed the
inion that "the need for efficient physicians and
rgeons in the field and at home is not less urgent
an the need for efficient soldiers and sailors";
d I said that I had "felt it my duty to press this
nsideration on senior students, who, though they
ve nearly completed their curriculum, are ready
forego the prospect of early qualification and to
rol themselves straightway in the combatant
ces."[1]

To-day I have received a letter from Surgeon-
neral Sir Alfred Keogh, which contains the
lowing passage: "I think with you that the
ıior student is best fulfilling his duty to the
ıntry by getting his degree and then joining the
ny. The need for young qualified men will
come great, and I should regret that the supply
ould be diminished."

As I daily receive letters from senior students
d their parents who desire guidance in their
oice of apparently conflicting duties, I shall be
ateful if you will make known the opinion held
the War Office on the subject.

I am, Sir, yours faithfully,

DONALD MACALISTER,
President, General Medical Council.
edical Council Office, Oxford-street, W., Dec. 10th, 1914.

---

[1] THE LANCET, Nov. 28th, 1914, p. 1280.

THE TREATMENT OF TETANUS.

To the Editor of THE LANCET.

SIR,—In 1910 I read a paper at the Royal Society of Medicine on the treatment of tetanus by the intraspinal injection of a 25 per cent. solution of magnesium sulphate. This is given in addition to the ordinary antitoxin treatment. In seven cases in which I used the method four recovered, three of them being very severe cases. In one of the fatal cases it is very doubtful if the fluid was injected intraspinally. I referred to 21 cases, with 12 recoveries.

Lumbar puncture is performed in the usual way and fluid withdrawn; this is replaced by the magnesium sulphate solution in the proportion of 1 c.c. for each 25 pounds of body weight. This makes about 5 to 6 c.c. for an ordinary adult. The lordosis and opisthotonos make this at times difficult. The body should be propped up slightly afterwards to prevent the fluid reaching the medulla and causing respiratory failure (in a recorded case artificial respiration was effective); the result is flaccidity of the lower limbs and abdominal muscles, and very often the trismus diminishes. With this relief to spasm sleep often comes on. It should be repeated as often as is necessary; sometimes it has to be repeated within the 24 hours. In one of my cases 16 injections were given without any bad results; some of the later injections were larger, but no cumulative effect was seen.

The treatment is not free from danger. The principal risk is respiratory failure; prolonged artificial respiration is the remedy for this. Bronchorrhœa has been recorded, but I have seen this in tetanus in a case treated only by antitoxin. Retention of urine is also common after this treatment. The spinal canal might be repunctured and the magnesium sulphate solution washed out if respiratory failure occurs. For the bronchorrhœa atropine hypodermically has been advised. I have advocated the method as an adjuvant to the ordinary antitoxin treatment as a means of obtaining rest and preventing exhaustion from the spasms whilst the body is overcoming the toxæmia. Magnesium sulphate has also been used subcutaneously and good results have been claimed for it, but I have no personal acquaintance with the methods.—I am, Sir, yours faithfully,

LLEWELLYN PHILLIPS,
Professor of Medicine in the Egyptian Government Medical School, Cairo.
Nov. 27th, 1914.

To the Editor of THE LANCET.

SIR,—In the very valuable and instructive discussion on the treatment of tetanus at the Medical Society of London, abstracted in THE LANCET of Dec. 12th, and also in your leading article in the same issue very little mention is made of anaphylaxis—I mean of true anaphylaxis as opposed to "serum sickness." It seems to me that a favourable opportunity is now offered, when so many injections of serum are being used for prophylactic and curative purposes in tetanus and other diseases, to observe this phenomenon should it occur.

All who have studied Professor Richet's work[1] must have been deeply impressed by his observations. Personally, I am inclined to think anaphylaxis is not a regular or even common phenomenon in the most favourable circumstances. Some years ago Dr. Murray Bligh and I made many observations and found it more difficult to obtain experimentally than we had been led to suppose by the writings of others. At the same time, of course, it may, and does, occur that an animal or human being is sensitised by a dose of foreign protein—e.g., serum—and dies suddenly on the administration subsequently of the smallest dose of the same protein after and within a certain time. It is, therefore, a matter of considerable importance that valuable lives should not be risked at the present time in the circumstances which now exist as regards serum production and therapy, when by simple measures all danger can be eliminated. Sera are given so often and with so little regard for the future—so far as the possibility of anaphylaxis is concerned—that it seems worth while to consider whether we should not take steps at once to mitigate the danger of which I have spoken.

---

[1] English translation by J. Murray Bligh.

Sera are, I believe, at present practically all taken from immunised horses. Surely it would be a wiser course to immunise several different species of the larger animals with the various organisms against which horses are now commonly immunised. If this were done anaphylaxis, which is absolutely specific to the serum of any given species, could be certainly guarded against by using the sera of different animals, immunised against the same organisms, when more than one dose of serum was administered to the same individual after a short interval and within, say, 12 months, and each individual so treated should receive a card, or be marked in some way, for the instruction of those who treat him subsequently.

The matter is one of urgency and gravity; either there is no such thing as anaphylaxis or the course I have mentioned should immediately be adopted by those responsible for the preparation of the various sera.

Meanwhile, it may be worth while to remember that it is said that the fatal phenomena of anaphylaxis can be avoided if the serum be administered while the patient is under the influence of ether. I think we may disregard the statement that to produce anaphylaxis the two injections must be made in identical sites—subcutaneous, intrathecal, &c.

I should also like to allude to another point concerning the administration of sera. Susceptible subjects may be made seriously ill with "serum sickness"; but this can be prevented, or subsequently mitigated, by the administration of large doses of calcium salts by the mouth; three doses, each consisting of two ounces of the liq. calcii lactat. B.P. Codex in half a pint of water, should be administered with four-hourly intervals on the day on which the serum is administered or the "sickness" develops. I can testify to the value of calcium lactate in these circumstances from a personal experience.—I am, Sir, yours faithfully,

Liverpool, Dec. 14th, 1914. W. BLAIR BELL.

MEDICAL EDUCATION OF WOMEN IN LONDON.

To the Editor of THE LANCET.

SIR,—The increase in the number of women entering upon the study of medicine in London makes it urgently necessary to increase the laboratory accommodation of the London (Royal Free Hospital) School of Medicine for Women. This is not a war appeal, but it appears to the council of the school to be justified even at a time like this by the need of the country for more doctors in the near future, and by the fact that this school is the only one in London at which women can obtain a medical education.

The school deserves help for its work in the past. Founded 40 years ago, when there were only two women on the British Medical Register, there are now about 1000, of whom over 600 are former students of the school.

The school deserves help for the work it is doing now. The annual entry has doubled in the last six years. 212 students are in attendance, and if the present annual entry be maintained this number will rapidly rise to 300. It is a school of the University of London in the Faculty of Medicine. It has beautiful and suitable premises built 1899–1900, but they are not large enough for the present number of students. Additions to the laboratories, new research rooms, and more lecture rooms are essential. An adjoining site has been secured. Plans are prepared and approved, and building is to begin directly after Christmas.

The school deserves help for the work of the future. The demand for medical women constantly increases. In public departments throughout this kingdom, in sanatoria, in Poor-law institutions, in hospitals both in England and India, and as medical missionaries all over the world, they work in ever-growing numbers. At the present time medical women are urgently called upon to fill the places and supplement the work of the medical men serving with the army, and they are doing this both in this country and in France, so far as their numbers permit. This demand will be increased in the near future owing to the number of young men now joining the army, who might otherwise have studied medicine. Were twice as many to qualify as qualify now, all would be absorbed by these and other needs.

The council must raise £25,000 to pay for the additional buildings required and their equipment, and ask those interested in the work and medical education of women to provide this sum. Donations or promises should be sent to the London (Royal Free Hospital) School of Medicine for Women, 8, Hunter-street, W.C., addressed to the honorary treasurer, Mr. M. J. Henderson, who joins with us in the appeal.

We are, Sir, yours faithfully,
E. GARRETT-ANDERSON, President.
F. D. ACLAND, Chairman.
LOUISA B. ALDRICH-BLAKE, Dean.
MAY THORNE, Hon. Secretary.

London (Royal Free Hospital) School of Medicine for Women,
Dec. 14th, 1914.

THE ETIOLOGY OF LEPROSY.

To the Editor of THE LANCET.

SIR,—The letters in THE LANCET during August and September under the heading of "The Relation of Fish to Leprosy" induce me to raise briefly the question of the etiology of leprosy, which goes rather beyond the question of fish, be it fresh, salt, decomposed, or other.

It is really high time that the consideration of a subject of such engrossing importance should be restricted to the recording of facts and to analogical reasoning. What is being done throughout the world to sift the family history of the leper? Speaking for parts of the tropics where leprosy occurs, and of which I have personal experience, I can say that existing conditions are little likely to favour the acquisition of etiological facts. A lamentable process through the magistrate's court, sometimes a stay in a police cell, may be the committal portal for admission to the leper asylum; the medical officer to the institution has probably already a large district under his charge for general medical practice, and in the time devoted to the institution will be up to date no doubt in experimental drug treatment of his patients; an annual report is returned showing numbers of admissions and removals, and perhaps also the number of tea parties and magazines generously contributed by charity. But where is to be found the anamnesis in respect of a single case of leprosy?

Points regarding leprosy that are known, humanly, are: It is a disease of man; amongst animals the nearest approach to leprosy is found in the rat; there is sufficient evidence to justify the belief that it spreads from man to man; it has been believed to be a hereditary disease, a point indicative of contagion; the means of contagion are probably personally intimate; the incubation period of the disease is probably long; its occurrence in childhood is very rare; no proof is forthcoming of specific infection being derived from food of any sort whatever, though food as a vehicle of convection from man to man cannot be eliminated; experimentally at least, if not in nature, the bacilli have been demonstrated in certain blood-sucking "insects."

The inquiry has to be a domestic investigation on the same lines as are followed by the health officer in relation to typhoid, diphtheria, tuberculosis. When our colonies can boast of an organised department of preventive medicine we may expect accumulation of records which should demonstrate inevitably the etiology of leprosy; as inevitably as the microscope shows the bacillus. Until then, perhaps, the millions available in the hands of the great pioneers of private research might be directed to the organised field investigation of leprosy as they now are of other diseases.

A leper institution is an awful thing.

I am, Sir, yours faithfully,
ANGUS MACDONALD, M.D. Edin.,
Grenada, B.W.I., Nov. 23rd, 1914. Medical Officer in Charge.

THE MORPHOLOGY OF THE TYPES OF TUBERCLE BACILLI FOUND IN MAN.

To the Editor of THE LANCET.

SIR,—In his interesting article which appeared in THE LANCET of Nov. 21st, Dr. Horace R. Wilson calls attention to the importance of observing the morphological characters of the tubercle bacilli in a tuberculous case as an aid in prognosis.

For many years past the great importance in prognosis of such observations has been emphasised by Carl Spengler in his published researches on tuberculosis.[1] In the routine examination of tuberculous material by his methods careful attention is always given to the determination of the degree of injury manifested by the sheaths of the tubercle bacilli. Sheath injury may arise from causes other than an increase of the immunity of the patient; hence care must be taken to minimise errors due to such causes. In the lectures on the bacteriology of tuberculosis delivered by me during the past two years in the bacteriological laboratories of King's College much attention has been devoted to the qualitative investigation—as distinct from the usual quantitative examination—of tubercle bacilli in tuberculous material. It may be helpful to note that Spengler's "pikrin" method and the modifications of it introduced by Kirchenstein and by the writer are specially adapted for the qualitative and structural investigations referred to; the Ziehl method is unsuitable.

Dr. Wilson mentions that two distinctly different types of tubercle bacilli are found in human sputa—viz., Type 1, short, plump bacilli taking a uniform stain; Type 2, longer, thinner bacilli with clear (unstained) spaces numerous and well marked, the stain less deeply taken. It is important to note that the two types of tubercle bacilli which Spengler has described, and which he has isolated from human sputa, have characters quite different from Types 1 and 2 mentioned above. Spengler maintains that in most cases it is possible to isolate two types of tubercle bacilli from tuberculous man—viz., typus humanus brevis (Koch), and typus humano-longus (Spengler). From his investigations he has concluded that by his methods it is possible microscopically to distinguish between these two types if the bacilli are fully developed.[2] The characteristics of the types have been given in a comparative form in previous contributions on the subject[3]; the following is a brief summary of the more important of the morphological details: 1. Humanus brevis is a thin, short type of tubercle bacillus. 2. Humano-longus is thicker and longer than humanus brevis; it is a bovinoid type of tubercle bacillus, closely related to, but not identical with, the true bovine tubercle bacillus of cattle. Both types when uninjured and fully developed stain uniformly with the "pikrin" method. Splitter formation—the so-called "beading"—occurs in both types and is associated with degenerative changes in the bacillary sheath to which allusion has already been made.

Although, as Dr. Wilson states, some investigators have been unable by their methods to distinguish microscopically between the bovine and human types of tubercle bacilli as defined by these workers, nevertheless it must be noted that up to the present no researches have been conducted by them upon the two types of tubercle bacilli in tuberculous man as described by Spengler.

In future investigations it seems very desirable that the subject should be approached from Spengler's standpoint.

I am, Sir, yours faithfully,
WALTER H. FEARIS.
Cardiff and County Public Health Laboratory, Dec. 11th, 1914.

THE INCIDENCE OF PLAGUE IN EUROPE.

To the Editor of THE LANCET.

SIR,—My attention has been called to an article by Mr. C. Strickland entitled "The Incidence of Plague in Europe" in THE LANCET of Nov. 14th last, in which he states that the probability of a plague epizootic occurring among brown rats in this country is 250 times less in the summer than in the winter. This conclusion is based upon data extracted from reports made to the Local Government Board in connexion with the epizootics of rat plague which occurred in East Anglia in the winter of 1910 and the autumn of 1911 respectively.

Mr. Strickland's argument appears to be somewhat as follows: Martin and Rowland found in the winter of 1910 a flea-rate of 1 flea per rat associated with an 11 per cent. plague epizootic, while in the summer of 1911 Strickland and Merriman found a flea-rate of 4·5 associated with a 0·2 per cent. epizootic. Hence, in spite of the flea factor being 4·5/1 stronger in the summer than in the winter, the adverse factor (which he assumes to be lessened density of rat population) is so powerful that the epizootic resulting is 0·2/11 or 1/55, and thus the chances of infection are lessened nearly 250 times.

[3] W. H. Fearis: The Treatment of Tuberculosis by Means of Immune Substances (I.K.). An introduction to Spengler's work on Tuberculosis and Immunity (John Murray), p. 3 et seq. Brit. Med. Jour., March 14th, 1914, p. 625.

The conclusions arrived at by Mr. Strickland give quite an erroneous impression with regard to the relative severity of the two epizootics, as he has failed to take into consideration the widely different circumstances in which the two investigations were conducted. The figure "11 per cent." that he quotes from Martin and Rowland's paper refers to the percentage infection found among 123 rats collected from specially selected areas where epizootic plague was either suspected or actually known to exist at the time of the inquiry. The flea-rate per rat for this series was, moreover, not 1, as Mr. Strickland states, but actually 2·7. During the investigation in 1911 some 15,000 rats were examined from a wide area comprising over 200 parishes, only 19 of such parishes proving to be plague infected. From personal knowledge I have no hesitation in stating that in some of these infected districts the rat mortality from plague was very high. It is quite true that only 35 plague-infected rats actually came to hand during the inquiry, but this result was not due to any scarcity of infected material, but rather to the fact that as soon as plague was officially diagnosed in any parish the supply of rats brought to the laboratory for examination from that source was immediately cut off. From these considerations it is apparent that the figures "0·2 per cent." do not give any indication of the percentage infection in the infected areas and that the assumption contained in Mr. Strickland's paper is quite unjustified.

I am, Sir, yours faithfully,

RALPH ST. JOHN BROOKS.

Lister Institute, Chelsea Gardens, S.W., Dec. 15th, 1914.

ANTISEPTIC TREATMENT OF WOUNDS.

To the Editor of THE LANCET.

SIR,—I have read in THE LANCET of Nov. 21st an address on the Treatment of Wounds in War by Sir W. Watson Cheyne. This arresting paragraph occurs in the address:—

> Giving my own experience of naval cases, all the wounds which I have yet come across have been septic, some of them very badly so; I hear also that those who are working at the army base hospitals are having a large amount of sepsis in shell and shrapnel wounds.

At the conclusion of his address Sir W. Watson Cheyne says:—

> The question I have been referring to is one of tremendous importance, and I entreat you to give it your most earnest consideration ...... Any day we may hear of the death of our boys in battle. If they die on the field of battle, they at least die nobly in fighting for their country and for the safety of those they leave behind. Surely it makes it still harder for us to know that if they escape death on the field of battle, they may still, as the result of imperfect disinfection of the wounds, die from sepsis, or be maimed for life. I beg of you to consider this matter calmly, and logically, and without prejudice, and see that every possible means is taken to avoid this great calamity.

These moving and eloquent words of the President of the Royal College of Surgeons of England are my reasons for writing this letter to you. For many years the treatment of injuries has been my principal work in Lancashire. Until recent years, do what I would, some 10 per cent. or more of such injuries became infected. For a long period I endeavoured by mechanical means and by the aid of antiseptics to prevent the infection of skin wounds, compound fractures, burns, &c., and finally came to the conclusion that it was impossible mechanically to remove septic organisms from an open wound, or to ensure by the application of antiseptics the destruction of infecting bacteria by any means known to me then.

About 10 years ago I began a research having for its object the elimination of sepsis from recent wounds. Lister's first work on the treatment of compound fractures was the inspiration for this research. He stirred up with the blood carbolic acid so as to form a sort of paste which filled up the wound, and by this means he was successful in avoiding sepsis in a large percentage of cases. It will, I think, be admitted that healing by aseptic blood clot and granulation is the object to be aimed at in accidental injuries where there is so much destruction and injury of the tissues that primary union of the skin is impossible. The idea in my mind when I began the research was to utilise the exudate from a recent wound—e.g., blood serum, lymph, &c.—for the protection of the injured tissues. Could this exudate be acted upon by an antiseptic solution in such a manner as to prevent septic infection of the wound? After many trials and many disappointments with various antiseptics I at length hit upon a satisfactory method of treatment.

It is, of course, well known that mercuric chloride, $HgCl_2$, is one of the most powerful germicides, but this agent in the pure state in solution combines so readily, and, as it were, so firmly with albumin, forming an albuminate of mercury, that it is unsuitable and ineffective for the treatment of recent wounds. I quote from "The Chemical Basis of Pharmacology," Francis and Fortescue-Brickdale:—

> The degree of dissociation which a substance undergoes on solution in water can play an important part in its action on the organism. Paul and Kronig investigated the antiseptic power of mercuric chloride, using the spores of B. anthracis, and found that in equimolecular solutions, the chloride was the most powerful antiseptic, then the bromide, and that the cyanide had least action. This corresponds to the degree of dissociation which takes place in the three solutions. The same authors investigated the antiseptic powers of a solution of perchloride of mercury and common salt. Many years ago Bacelli, when advising intravenous injections of mercurial salts in cases of syphilis, employed a solution of the perchloride, mixed with sodium chloride in the proportion of 1 to 3, which he stated to be more effective in actual practice.
>
> Paul and Kronig have shown that the actual process is as follows: A double salt is formed ($HgCl_2NaCl$) which dissociates into positive sodium ions and negative complex ions of mercury and chlorine. The latter are inactive from an antiseptic point of view, but a certain amount of secondary dissociation of the complex negative ions occurs, resulting in the formation of the active mercury ions, though to a smaller extent than when an equimolecular solution of mercuric chloride alone is employed. The action is thus hindered, but in practice the increased solubility which is obtained by the addition of salt, more than counterbalances the decreased ionic dissociation.
>
> The action of a drug appears to depend upon its possessing (1) some group of atoms capable of exerting a specific effect on the cell, and (2) another group or side chain capable of entering into some kind of chemico-physical relationship with certain cells, whereby the first is enabled to produce its action.

In experimenting on these lines (but in ignorance until quite recently of these observations) it occurred to me that the addition of calcic chloride to a solution of mercuric and sodic chloride might cause more rapid coagulation of the exudate than the mercury and salt alone; and that the double salt $HgCl_2CaCl_2$ would combine more loosely with albumin.

This I found to be the case, and also that the antiseptic power of the molecule thus formed was increased considerably. The outcome of all my experiments, which are too tedious and too voluminous to recapitulate here, was a solution containing mercuric, sodic, calcic, and potassic chlorides. To this compound the short name "hydrion" may be applied. That is "hydr-(argyrum)ions."

The formula for the antiseptic I use is as follows:—

	Grains.	Grammes.
Mercuric chloride ($HgCl_2$) ...	4·375 ...	0·283
Calcic chloride ($CaCl_2$)	1·86 ...	0·12
Sodic chloride (NaCl)	34·76 ...	2·252
Potassic chloride (KCl)	0·075 ...	0·005

Hydrion is therefore a double chloride of mercury and calcium dissolved in normal saline solution with the addition of a trace of potassium chloride. These quantities are made up into a 40-grain solid tablet. This tablet is very hygroscopic and must be kept dry. One of these tablets dissolved in a pint of cold water (or two to one litre making a rather stronger solution) forms the ordinary antiseptic solution which I use habitually for recent wounds on the hands, feet, head, and exposed parts generally. A somewhat weaker solution should be used on delicate skins, or on a skin which is usually covered by clothing. A much stronger solution is used in the first immersion of a very dirty wound. This solution is a thoroughly efficient sterilising agent. It is highly labile, and its chemico-physical properties admit of rapid dissociation in the medium in which it is required to act. It has great diffusibility; its osmotic power is great, and its powers of uniting with albumin are such that it is capable of being incorporated with the exudate from a wound in such a manner as to cause rapid coagulation of the exudate, thus plugging the vessels and wound at once with a tenacious clot in which bacteria do not grow. This coagulum either destroys the bacteria which may be present in the wound or it inhibits their growth and development.

To give an example. A man sustains a crushed hand at his work by being caught in a machine. His fingers are severely lacerated, he has compound fracture of several bones, tendons are exposed, &c. No attempt whatever is made mechanically to cleanse the wound. Any obvious gross foreign bodies are removed; the hand is dipped for five minutes in the *cold* solution; the parts are very gently pressed into something like normal position; all active bleeding points are compressed with forceps—no ligatures should be used. The whole of the injured area—that is, every particle of raw surface—is carefully covered with thin *pure* gutta-percha tissue. A *small* amount of wood-wool wadding is saturated with the solution and firmly pressed over the gutta-percha tissue. The whole of the injured part is then covered with an ordinary bandage, the object aimed at being to put on the *minimum* of dressing. The bandage should not be tight, but it should be firm; and finally the hand (bandage and all) is dipped into the solution. Tablets are given to the patient, one of which he is told to dissolve in a pint of *cold* water and to immerse the hand (dressing and all) at intervals of six hours. Such a dressing, bloodstained and dirty as it may become, can be kept on for three or four days without any risk of infection of the wound. My practice when there is much oozing in a bad wound is to change the dressing in 24 hours and to wash the whole injured area in the solution, then to deal with the wound according to its requirements—to suture the skin, to adjust broken bones, suture tendons, &c. I never use a splint in such an injury, but I encourage the man to move his fingers from the very beginning. No swelling will occur, no redness nor pain; but the skin which has been subjected to the action of the solution will be wrinkled, bleached, and soft, so that the cuticle can be easily removed together with all dirt and foreign matter on the hand. The coagulated blood clot should be disturbed as little as possible. The continued application for days or weeks of the solution does not injure the living tissues, and it is remarkable how rapidly the wound will heal under its influence. It is essential to keep the raw surface moist with the solution and covered with the gutta-percha tissue throughout the healing process.

Wounds inflicted on the battlefield should, at the earliest possible moment, be washed with the solution of hydrion, covered with gutta-percha tissue and then a thin layer of wood-wool or gauze (taking great care that the latter is not in contact with the wound), with a not tight bandage over all; the whole dressing should be soaked in the solution or thoroughly wetted in it every six hours or so. This method is simple, cheap, quick, and efficient. It must be understood that my experiments have been made on wounds infected with the ordinary pyogenic bacteria. It may be that the more resistant anaerobic spore-bearing organisms, such as those of tetanus, spreading gangrene, or gas gangrene, may not be affected by hydrion. I do not know, but in cases where their presence is suspected I would advise a stronger solution, to be applied more frequently. My recent work shows more than 1000 consecutive cases of injuries where there has been a breach of the skin surface treated within 24 hours of the infliction of such an injury without one case of infection of the living tissues. The use of the guttapercha tissue is essential. It keeps the clotted exudate moist with the solution; it prevents evaporation; and, most important of all, *it does not stick* to the clot, so that when the dressing is removed *the clot is not pulled away* (as it is with a gauze or other cellulose dressing), nor are the healing granulations injured and made to bleed. It also protects the clot from direct contamination through the dressing, but it allows constant irrigation of the wound by capillary attraction and osmosis at the edges of the gutta-percha tissue.

I have not had time to verify all my references nor to acknowledge my indebtedness to the many authors I have consulted on this subject. In some further communication I hope you will allow me to rectify this omission in a paper in which I will go more thoroughly into the experimental data upon which my method is based. If those members of my profession who do me the honour to read this letter are inclined at first to exclaim with Naaman the Syrian: "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel?" I hope they will do as Naaman did on second thoughts. If they will try this method of dressing a recent wound I believe the results will surprise them. I shall be glad to give further information on the subject to any colleague who cares to write to me.

Hydrion can be obtained in tablet form from Messrs. Hough, Hoseason, and Co., Sun Buildings, Bridge-street, Manchester, who have taken endless trouble in the preparation of these tablets for me.

I am, Sir, yours faithfully,
Thomas Lissaman.

Mornington House, Bolton, Dec. 7th, 1914.

*** Combinations of the perchloride of mercury with the alkaline chlorides have been proposed for some time with the view of producing a powerful antiseptic effect without the irritating properties of the mercuric salt alone; while so combined mercury does not quickly coagulate the albumin. The addition of calcium cloride is, however, a possibly important suggestion, having regard to its effect on the coagulability of the blood, and a looser combination with albumin is formed than when the perchloride is used alone.—Ed. L.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

During the last week the organisation of the Fund has been proceeded with steadily, and promises of coöperation have been received from universities, provincial centres, and individual medical men and pharmacists. A comprehensive scheme is at present being organised to appeal to all the doctors and pharmacists of Scotland on behalf of their Belgian brethren. The proposal here is for a large committee with representatives of the universities, the Royal Colleges of Physicians and Surgeons, Royal Faculty, and the Society of Pharmacists of Scotland. Progress is being made, we understand, with the movement. From Dublin we publish a long list of subscriptions received or promised, which has been forwarded to us from the Royal College of Physicians of Ireland. In Belfast the Ulster Medical Society and the Ulster branch of the British Medical Association are proposing to draw the attention of their members to the movement.

At a meeting of the Executive Committee of the Fund, held at the offices of the British Medical Association on Thursday, Dec. 10th, Mr. E. T. Neathercoat, Vice-President of the Pharmaceutical Society of Great Britain, was elected a member of the Committee, and the following nominations upon the General Committee, made by the Pharmaceutical Society of Great Britain, were accepted unanimously:—Mr. Edmund White, President of the Pharmaceutical Society of Great Britain; Mr. J. H. Cuff, Mr. W. H. Gibson, Mr. R. L. Gifford, Mr. A. Hagon, Mr. P. F. Rowsell, Mr. G. E. Pearson (Messrs. Burroughs, Wellcome, and Co.), Mr. F. P. Sargeant, Mr. W. S. Glyn-Jones, M.P., Mr. J. C. Umney, Mr. D. Gilmour, Mr. J. P. Gilmour, Mr. W. L. Currie, Mr. T. Guthrie, and Mr. J. Rutherford Hill. The addition to the General Committee also of the names of Mr. Lynn Thomas, Vice-Chancellor of the University of Wales, and Professor E. W. Hope, of Liverpool, was agreed to.

Address by Professor Jacobs.

A meeting of the Edinburgh Obstetrical Society was held on Dec. 9th, Sir J. Halliday Croom, the President, being in the chair, when Professor Jacobs, of Brussels, gave an address on "The Position of the Medical Profession in Belgium." A reception of the Fellows to welcome Professor Jacobs was given by the President, who, in introducing Professor Jacobs, eulogised the action of Belgium and referred to the great losses it had incurred in coming to the help of the Allies.

Professor Jacobs, who was most cordially received, recounted the sufferings of his country in this terrible war. When the Belgians heard of the declaration of war they to a man decided to defend their neutrality; they considered it was their duty to do so. Their country had suffered terribly. Doctors had not been spared; they were also bearing their heavy share. They were devoting their care, and if necessary their lives, to their country. But they had no medical stores; their homes and pharmacies were ruined. Was it realised what they were suffering? They were trying faithfully to fulfil their duty by remaining at their post. Some were carrying on their practice in ruined buildings. They were endeavouring to sustain their wives and children, and at the same time doing their best to alleviate the misery among them. Some doctors had had to work as navvies. Some had had to sell what had been spared by the Germans. Professor Jacobs had met a doctor who had not eaten bread for a fortnight, living only on potatoes. Some had to lie on straw for beds. One had his only pair of boots on his feet, and these falling to pieces; others had only torn garments to clothe themselves with. One had to live for three days on wayside herbs, and his wife shared his fate. Another was searching in vain for six or seven days for his wife and family in the country around. Some doctors had been imprisoned as hostages; some had been shot. One, the burgomaster of a place near Liége, was seized, had his ears cut off, his eyes gouged out, and was then shot; afterwards his head was carried on the end of the lance of an Uhlan through the town. There were widows and orphans of doctors deprived of everything. A doctor and his son were shot before the eyes of the wife. As head of the Belgian Red Cross Professor Jacobs visited a chateau, but found the Red Cross had not been respected; it had been completely destroyed and the bodies of six girls, aged from 10 to 17, were lying on the lawn. A convent containing 60 sisters had been entered by the German soldiers and every one had been violated; on the evidence of the doctor to the institution 25 were pregnant. Professor Jacobs had operated on the wife of a doctor living near Namur. Three weeks after the operation when convalescing and still in bed their house was entered by German soldiers; she was raped by seven of them and died two days afterwards. Many civilians had been shot; some places had only a few inhabitants left out of hundreds. In Dinant more than 900 had been shot and the town razed. Professor Jacobs was in his house in Brussels when the Germans occupied the city, and the military were disposed in the houses. Some came to his house and he recognised German professors whom he had some acquaintance with. He could not shake hands with them, but gave them beds. They left early in the morning, and on entering his operating room he found they had stolen his instruments. Professor Jacobs closed his address with some lantern slides of the ruins of Louvain and other places.

The Peterborough Pharmacists' Association has led the way on behalf of pharmaceutical associations with a contribution of £7 2*s.*, and it is to be hoped that every association throughout Great Britain will follow this lead. The Pharmaceutical Society of Great Britain has sent a generous contribution of £50. A register of all Belgian pharmacists in Great Britain has been compiled, and although perhaps somewhat imperfect at the moment is being steadily amended day by day. A very large number of Belgian pharmacists have personally called on the secretary of the Pharmaceutical Society at 17, Bloomsbury-square, and for many of them work has been found. There are, however, several names registered as wanting situations, and any pharmacist who can offer suitable work should communicate with Mr. W. J. Uglow Woolcock.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund and crossed Lloyd's Bank, Limited. These will be acknowledged by post direct, and a list will appear in THE LANCET weekly.

The following subscriptions to the Fund have been received by Dr. Des Vœux up to Tuesday evening last, in addition to subscriptions amounting to £1444 previously acknowledged :—

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments, &c., kindly contributed by the following donors since the publication of the last list:—

Dr. A. E. Whitehead, Bridlington (two contributions); Anonymous, Birvie, Montrose; Dr. M. H. Taylor, Johnstone; Dr. Norman Davidson, Peterhead; Dr. W. H. Webster, Castle Cliff, Ventnor; Dr. F. J. Allan, Public Health Department, Westminster; Dr. Harris, Southport; Dr. Isdale Greig, Kirkcaldy; Dr. F. Johnston, Birkenhead; Dr. George Hill, Birkenhead; Dr. J. H. Fardon, Birkenhead; Dr. W. A. Pierce, Birkenhead; Dr. H. L. Pearson, Birkenhead; Dr. H. N. Harrington, Birkenhead; Dr. L. D. Temple, Birkenhead; Mr. F. C. Cooling, Birkenhead; Mr. A. H. Ellithorne, Birkenhead; Mr. S. Robinson, Birkenhead; Miss Robinson, Birkenhead; Dr. R. Broughton Knowles, Primrose Club, St. James's, S.W.; Mr. William Baker, Hon. Director, Dr. Barnardo's Homes; Dr. E. W. S. Evans, Mark-lane, E.C.; Dr. Bramley Taylor, Weybridge; Dr. Willson, Weybridge; Mr. G. Carnock Sawday, Weybridge; Mrs. R. Musgrave Craven, Grove Park, Wanstead; Dr. John T. Leon, Southsea; Dr. H. W. Saunders, Eastbourne; Dr. W. J. Harnet (second contribution), Barnet; Dr. J. Robertson Crease, South Shields.

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.—The governors of this institution having been unable, owing to the heavy demand for medical men for military purposes, to obtain men for the posts of three resident medical officers who have been called up for service, have appointed three medical women to fill the vacancies.

SIR JOHN STRUTHERS LECTURESHIP.—Dr. Johnson Symington, F.R.S., Professor of Anatomy, Queen's University, Belfast, delivered the second of the Struthers Lectures in the hall of the Royal College of Surgeons of Edinburgh on Dec. 16th, the subject being "Observations on the Relations of the Inner Surface of the Cranial Wall to the Outer Surface of the Brain." The lecture was illustrated by specimens, casts, and photographs.

KING EDWARD'S HOSPITAL FUND.—On Dec. 16th a meeting of this fund was held at St. James's Palace for the purpose of awarding grants. In the absence of the Duke of Teck the Speaker of the House of Commons presided, and read a letter from Lord Stamfordham expressing the King's hope that the needs of voluntary hospitals would not be lost sight of during the present crisis, and recording His Majesty's grateful appreciation of the service of those who had worked on behalf of the fund. The sum distributed amounted to £140,000.

THE WAR.

THE CASUALTY LIST.

THE following casualties among officers of the Royal Army Medical Corps have been reported since our last issue:—

Wounded: Captain G. H. Stack and Captain A. C. Osburn.

Prisoners of war: Major A. G. Thompson, Lieutenant J. R. Hayman, and Lieutenant W. A. Russell.

We trust that the unofficial report, through private sources, that Captain Angus McNab, medical officer of the 1st Battalion, London Scottish Regiment, is not dead but a prisoner of war may prove to be correct. He was officially reported killed in action.

VOLUNTARY HOSPITALS IN FRANCE.

The British Red Cross Society announces, on the authority of the War Office, that no further voluntary hospitals whatever are required at present for the British Expeditionary Force in France, and that any voluntary hospitals at present on the continent, or which may at some future time proceed to the continent, will work as base hospitals only, and will not be allowed to proceed further.

THE WAR AND THE NATION'S DRUG-SUPPLY.

The December evening meeting of the Pharmaceutical Society was devoted to the reading of five papers on the effect of the war on the nation's drug-supply, and the subject was dealt with from every standpoint. It is, of course, common knowledge that immediately after the outbreak of war there were substantial advances in the prices of a large number of medicinal products, but it is, perhaps, not so well known that had it not been for certain actions taken by the Government in consultation with an advisory committee consisting of manufacturing chemists and pharmacists prices would most probably have risen to a much higher level. As one of the contributors to the discussion, Mr. J. C. Umney, pointed out, the action of the Government by their inquiries and legislative power for acquisition had the effect of levelling prices from the range of fancy to fact within the short space of two or three weeks. The prohibition of the export of certain drugs was also an important factor in preventing the depletion of stocks. With regard to synthetic products and certain other chemical substances made in Germany Mr. C. A. Hill observed that the reason why stocks of these had not run out completely was that the high prices had checked the consumption, and in consequence the reduced demand had prevented an absolute famine. "After four months," he added, "we do not find ourselves without many necessaries." Mr. Hill discussed the prospects of the establishment in this country of the manufacture of synthetic drugs. "We have," he said, "the chemical knowledge in this country, and at a price it could be done. It may not be done all at once, but it can be done in time ...... but it means trial and error, special plant, time and money; and this raises the difficulty, of which we have naturally heard so much of late—security for the future for a sufficient period to admit an adequate return on capital outlay." Professor H. G. Greenish discussed the question from the standpoint of vegetable drugs and advocated increased attention to the cultivation of medicinal plants in suitable parts of the British Empire. He also suggested the desirability of finding substitutes for drugs, the supply of which has been seriously curtailed. "The word substitute," he admitted, "has a somewhat objectionable sound, but if we look at the Indian and Colonial Addendum to the Pharmacopœia we shall find a number of drugs and preparations which in certain limited areas may be used in the place of others—that is, substituted for them. Thus, butea gum may replace kino, black catechu may replace catechu, and so on. Such drugs have been called 'parallel drugs'—their number is by no means small." Mr. F. W. Gamble contributed to the discussion an interesting statement with regard to the effect of the war on the supply and demand for serums and vaccines. Immediately on the outbreak of war a large demand arose for calf lymph and typhoid vaccines. There was also a demand for antisepsis vaccine and tetanus antitoxin. The amount of tetanus antitoxin occurring normally in this country is quite small, and the supply of serum ready prepared was therefore soon exhausted, but fortunately large stocks of the antitoxin were available from America, and the additional requirements are being supplied with American serum until British production is increased. Mr. R. R. Bennett dealt with the supply of drugs and chemicals the manufacture of which is protected by patents owned by Germans, and substances commonly known by a name in which there exist trade-mark rights owned by an alien enemy.

THE BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Dec. 12th states that the number of auxiliary Home Red Cross Hospitals accepted by the War Office to date is 598, containing beds for 16,950, including 678 beds, accepted during the past week, and distributed among the Army Commands, as follows:—London, 933; Southern, 5445; Aldershot, 796; Eastern, 4324; Northern, 2610; Western, 2641; Irish, 201. A number of Red Cross Voluntary Aid Detachments are being utilised in connexion with these hospitals.

The British Red Cross Hospital at Netley is now in working order, and the Maxine Elliott operating theatre has been taken into use. The plans for the new extension of 200 beds given by Lord Iveagh have been prepared, and contracts are being entered into. This addition to the hospital should be in full working order by the end of January. The medical personnel is as follows:—Commandant: Surgeon Lieutenant-Colonel Sir Warren R. Crooke-Lawless. Registrar and Secretary: Captain J. L. Dickie, M.B. Senior Physician: Major C. H. Miller. Senior Surgeon: Major C. Wallace. Staff Surgeons, Physicians, and Specialists: Captain C. Christopherson, Captain J. A. Hayward, Captain D. C. Nitch, Captain H. L. Tidy, Captain A. C. Hudson, Lieutenant W. Anderson, Lieutenant M. S. Esler, Lieutenant J. C. Ferguson, Lieutenant C. Gibson, Lieutenant J. D. Lyle, Lieutenant J. F. Mackay, Lieutenant E. C. Norbury, Lieutenant C. Pearson, Mr. D. B. Pascall, and Mr. W. G. Marsden.

There have been despatched during the week 12 motor ambulances and one lorry to Dunkirk; six ambulances, four touring cars, one lorry, and a motor cycle to Boulogne, and two ambulances to Havre. The motor ambulances which have been despatched to date number 700.

The British Hospital at Wimereux, Boulogne, which was equipped and opened in the Hôtel Bellevue on Nov. 12th, has been inspected by Colonel Barefoot and declared to be "a most excellent little unit." It has its own private fleet of six motor ambulances, motor lorry, and two cars. The military medical officer in command is Lieutenant-Colonel Copeland, R.A.M.C.; chief surgeon, Major H. M. W. Gray, F.R.C.S., R A.M.C. (T.); the assistant surgeons, Dr. A. H. Rabagliati, M.D., F.R.C.S., and Mr. William Pearson, F.R.C.S.; the physician, Lieutenant-Colonel A. H. Lister, M.D., R.A.M.C.(T.); and the radiographer, Mr. P. Lake-Hope, M.R.C.S. The hospital has 102 beds (12 of which are for officers), and during the first month there were admitted—officers, 25; other ranks, 456; prisoners of war, 3; total, 484.

453 cases of stores and garments were despatched abroad during the week; of these, the greater portion were sent to Boulogne, Calais, and Dunkirk. 215 hospitals in this country were supplied with 479 cases of stores. In consequence of the recent lull in the fighting, the extreme pressure that existed previous to the middle of November has been considerably relaxed. Moreover, the military stores in France are at present very fully stocked, and can now supply all the army hospitals abroad with such stores as are included in the War Office Schedules. This statement is made upon the authority of the Director-General of the Army Medical Service. Under these circumstances the British Red Cross Society is only called upon to supply its own hospitals, and to supplement the military hospitals by furnishing such stores as are not included in the schedules above mentioned. It is practically certain that emergencies—similar to that which occurred in the last week of October and the first fortnight of November—will again arise. It is equally certain that, under such conditions, the Royal Army Medical Corps will gladly welcome all stores that the Red Cross Society can send into France.

The following procedure has consequently been laid down, and has been approved by the Director-General of the Army Medical Service:—1. As long as the present conditions last, and as long as no sudden and unexpected demand arises, the Stores Department of the Red Cross will continue to supply the following: (*a*) the hospitals abroad, actually under its own authority, and for which it is directly responsible; (*b*) the ambulance trains, with comforts and garments; (*c*) the rest stations, at or near Boulogne; (*d*) the ambulance ships, with garments for the wounded; (*e*) the military hospitals abroad, with such comforts and garments as are not included in the Army Schedule and which it may wish to provide. 2. Should the present conditions change and an emergency arise, involving a large and sudden increase in the sick and wounded arriving at Boulogne or any other base, the Stores Department will assist the Royal Army Medical Corps to the utmost of its power by sending over stores of all descriptions to France in large quantities and in the quickest possible time.

The consulting staff of the King George Red Cross Hospital of 1650 beds, which is being established in the buildings of the new Stationery Office, near Waterloo Station, has been announced as follows:—

Consulting Physicians: Sir Thomas Barlow, Bart., Dr. J. Mitchell Bruce, Sir Bertrand Dawson, Sir H. Bryan Donkin, Sir Dyce Duckworth, Bart., Sir James Goodhart, Bart., and Sir Seymour Sharkey.

Consulting Surgeons: Sir W. Watson Cheyne, Bart., Sir Rickman J. Godlee, Bart., Mr. J. Warrington Haward, Sir Henry Morris, Bart., and Mr. Edmund Owen.

THE FRENCH RED CROSS.—The London Committee of the Croix Rouge Française has now been reconstituted and has its headquarters at 25, Knightsbridge, Hyde Park Corner, S.W. The president is the Viscontesse de la Panouse, and the honorary committee includes the French Ambassador, the Duchesses of Norfolk, Somerset, Devonshire, Marlborough, Roxburghe, and Wellington, and a number of other distinguished ladies. The executive committee includes the president, Madame Brasier de Thuy (vice-president), Comtesse de Saint-Seine (treasurer-general), Mme. Phalempin (secretary-general), Mrs. N. Lake (honorary treasurer), Mr. P. A. Wilkins (honorary secretary), and Dr. James Donelan (medical referee). A number of surgeons have already been sent out to France, and reports received from them indicate that very satisfactory work is being accomplished. Two well-known Dublin surgeons, Mr. R. Atkinson Stoney and Mr. H. S. Meade, have lately left to serve with the French Red Cross.

The first motor ambulance convoy organised for the Croix Rouge Française by the British Ambulance Committee for service at the front is to be despatched immediately. It will consist of 25 ambulances, driven by the owners or their chauffeurs, or by mechanics appointed by the Committee. It is to be under the control of a representative of the British

Ambulance Committee in all matters relating to the management or scope of work. Thanks to the promptitude with which M. Millerand, the French War Minister, responded to the overtures made to him by the British Ambulance Committee, and the manner in which Mr. B. Peyman, the secretary of the Committee, was received at Bordeaux, the despatch of the convoy has been greatly expedited. The Committee are in urgent want of a repair lorry to accompany the convoys despatched, the cost of each such auxiliary being approximately £550, while the need of more funds for general purposes is pressing.

EUROPEAN AMBULANCE WAR FUND.—The Ambulance Department of the Order of St. John of Jerusalem has issued an appeal for renewed support because of the growing demands upon its resources. From all parts of Great Britain, from France and Belgium and Serbia, from Indian camps and hospital ships, from ambulance trains and motor convoys, come the most urgent appeals for clothing, bedding, surgical dressings, hospital comforts, and for warm garments for convalescents. Everything that is warm and useful and clean is wanted, everything that a wounded man or a sick man needs, from the time that his war-worn uniform is taken from him in hospital. The address for all contributions is the President, St. John Warehouse, 56, St. John-square, Clerkenwell, E.C.

THE Council of the Royal College of Surgeons of England has appointed Sir W. Watson Cheyne, president, to serve on the Professional Classes War Relief Council, which, as already explained in these columns, has been formed to deal with distress among the professional classes directly due to the war.

THE MILITARY EXHIBIT AT THE HISTORICAL MEDICAL MUSEUM.—At the Wellcome Historical Medical Museum in Wigmore-street Mr. Henry S. Wellcome has conceived the timely idea of collecting together a special exhibit of interesting objects and relics associated with naval and military medicine and surgery, nursing, and ambulance. In addition to items previously in the museum, such as Lord Nelson's medical cabinet and the medicine chest of the Duke of Wellington, the selection includes a number of things lent by the museum of the Royal Army Medical College, certain London hospitals, and some private owners. Among these are relics of Dr. Gillespie, R.N., who was surgeon-general to Nelson's fleet; a letter from George Washington, dated Philadelphia, Feb. 20th, 1785, enclosing $60 in payment for a denture, a fragment of which appears in the case; a case of dental instruments that belonged to Napoleon I., and a French army surgeon's field pouch of 1862, which contains also a number of pistol cartridges. In the same show-case is a sample of the first field dressing issued to the British army for use in the Crimean War, and close to it is one supplied by Burroughs, Wellcome, and Co. for use in the Ashantee War. An especially interesting exhibit is the first electric bullet detector, devised by Sir Thomas Longmore, which consists of zinc and copper plates with a field compass in circuit and attached to probes. Close by is Dr. Wilde's electric alarum bullet indicator, a much more elaborate affair, in a mahogany case with bell, battery, and forceps. Another case illustrates the development of the tourniquet, beginning with Paré's original "leather thong," near it are Morel's (1678), which consists simply of a band and cord with a twisting peg, that of Dionis (1780), in which two twisting sticks are used, and various improvements thereon made in the eighteenth century by the German Richter, the Italian Assalini, and the Frenchman Savigny. Petit's tourniquet dates from 1712, and of this various specimens are shown, including that of Freke (1734), of St. Bartholomew's Hospital, who attached a spring cog to prevent loosening. Among the tourniquets must be mentioned the actual one used in the amputation of Nelson's arm at Teneriffe in 1797. Various artery compressors, a bandage winder of the eighteenth century, and a nurse's bandage carrier resembling a lady's chatelaine in bone, are in this case. A Forfex excisoria of the sixteenth century for extracting arrowheads and various forms of bullet extractors dating from 1535 onwards are of interest. A copy of William Clowes' "Book of Observations" (1637) depicting the instruments used in treating wounds is shown. Surgical instruments gathered on the battlefields of Vittoria (1813) and Waterloo, and an early eighteenth century case that belonged to the French garrison at Strassburg, are also to be seen. Downstairs a case contains a number of models of stretchers extemporised by the Japanese from various available materials, which display remarkable ingenuity. Another case shows the evolution of the splint, beginning with those of various native tribes. The Malayan splints are of particularly fine character. There is a fine exhibit of relics of Florence Nightingale, including several autograph letters from her, two dating from Scutari in 1855; also a collection of portraits, engravings, and so on, illustrative of her career, among which must be especially noted the original oil painting by Barraud, depicting her writing a letter for a wounded soldier, the engraving of which is widely known. There is also a fine panel portrait of William Clowes (1540–1604), "Naval and Military Surgeon to St. Bartholomew's Hospital," and Physician-in-Ordinary to Queen Elizabeth. One of the most interesting and topical exhibits, however, is a couple of postcards from a sergeant of the R.A.M.C. in France, with clever caricature pictures drawn in pencil on the special French Government post-card, and coloured with tincture of iodine and permanganate of potash by means of a brush made out of a match and absorbent cotton. They show considerable artistic talent. We have no doubt that this special section of the museum will excite no little interest.

ABERDEEN UNIVERSITY AND THE WAR.—At a meeting of the University Court of the University of Aberdeen held on Dec. 8th Principal George Adam Smith said that a provisional list up to Nov. 30th last showed that there were on naval and military service 330 graduates or alumni of the University, 266 students, and 79 students with the Officers Training Corps, making a total of 675. The Principal said this number would, no doubt, be largely added to before a final roll of members of the University on active service was completed. At the same meeting the gift was announced of £4000 from Mr. George Skelton Yuill, to encourage the practical application of the theory and science of chemistry to the arts, manufactures, and industries of Great Britain.

Sir Courtauld Thomson has been appointed Commissioner to the Order of St. John of Jerusalem and the British Red Cross Society, with the rank of lieutenant-colonel with the British army in the field, and will act under Surgeon-General Sir Arthur Sloggett, joint Director-General of the Army Medical Service and Chief Commissioner to the associated organisations.

Surgeon-General William D. C. Williams, C.B., Director-General of the Army Medical Service, Australian Imperial Forces, has reached London on business relating to the medical services of the Australian military contingent.

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that there are one or two vacancies for officers, who must be qualified medical men, in the 2nd South Midland Mounted Brigade Field Ambulance, R.A.M.C. (T). Reserve. Full particulars can be obtained of the Officer Commanding, Headquarters, Great Missenden, Bucks.

WE announce with much regret the death of Mr. Bernard Pitts, consulting surgeon to St. Thomas's Hospital and to the Hospital for Sick Children, Great Ormond-street.

DONATIONS AND BEQUESTS.—A sum of £500 has been bequeathed to the Aberdeen Royal Infirmary by the late Mr. James Ross, of Easter Beltie, advocate in Aberdeen.

SCARLET FEVER IN BELFAST.—At a meeting of the Public Health Committee of the city of Belfast, on Dec. 10th, after the receipt of reports from the medical officer of health and from the visiting physician to the Municipal Fever Hospital in regard to the serious epidemic of scarlet fever which has for years been prevalent in Belfast, it was decided to close the public or national schools for a period of five weeks—that is, from Dec. 14th until Jan. 18th of next year. The Public Health Committee hope that this interregnum will give an opportunity for any existing infection to exhaust itself, and will also afford a time during which the schools can be disinfected.

Medical News.

University of Oxford.—At a Congregation held on Dec. 12th the following medical degrees were conferred :—

B.M.—F. W. Browne, Wadham ; W. Brown, Christ Church ; H. G. Morris, University ; G. A. Maling and G. S. Robinson, Exeter ; B. E. Wall, Lincoln ; V. T. Ellwood, Pembroke ; C. H. Carlton, St. John's ; L. R. Broster, Trinity ; F. C. Gladstone, Pembroke ; and H. M. Pope, Lincoln.

University of Cambridge.—At a Congregation held on Dec. 11th the following medical degrees were conferred :—

M.B.—H. Hartridge, King's ; and C. R. A. Thacker, Downing.

Royal College of Surgeons of England.—As the result of the Final Fellowship Examination held on Nov. 19th, 23rd, 24th, and 25th last, for which 34 candidates presented themselves, of whom 11 acquitted themselves satisfactorily (including two candidates who have not yet complied with the regulations), the Council at its meeting on Dec. 10th conferred diplomas of Fellow upon the following nine candidates:—

Robert Neville Geach, M.R.C.S., L.R.C.P., St. Bartholomew's and Middlesex Hospitals ; Douglas Walker Hume, M.B., B.S. Lond., M.R.C.S., L.R.C.P., and Charles Noon, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital ; Gerald Waddington Beresford, M.R.C.S., L.R.C.P., London Hospital ; John Hamilton Barclay, M.B., B.S. Durh., M.R.C.S., L.R.C.P., Durham University and London Hospital ; Bernard Whitchurch Howell, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital ; Philip Geoffry Doyne, B.A. Oxon., M.R.C.S., L.R.C.P., Oxford University and St. Thomas's Hospital ; Ralph Marsh de Mowbray, M.R.C.S., L R.C.P., St. Thomas's Hospital ; and Douglas Green, M.B., B.S. Lond., Sheffield University and St. Bartholomew's Hospital.

Diplomas of Member were conferred upon the following three ladies and one gentleman who have passed the requisite examinations and have now complied with the by-laws of the College :—

Mabel Kate Bishopp and Hilda Grace Johnson, Royal Free Hospital ; James Hales Parry, Cambridge University and Guy's Hospital ; and Mary Woods, Royal Free Hospital.

Licences to practise Dentistry were conferred upon the following 35 candidates who have passed the requisite examinations and complied with the by-laws :—

Sidney Roland Bacon, Middlesex and Royal Dental Hospitals ; James Millard Barnes, Guy's Hospital ; Albert Edward Barnett and Roland Harry Bebb, L.D.S. Glasg., Birmingham University ; Montague Kempston Butler, Middlesex and Royal Dental Hospitals ; Henry Claude Carter, Middlesex and National Dental Hospitals ; Herbert Cartman, Manchester University ; Louis Edmund Claremont, Middlesex and Royal Dental Hospitals ; Walter Ernest Coe, Guy's Hospital ; Walter Tyrrell Cooper, Charing Cross and Royal Dental Hospitals ; Cyril James Crocker, Guy's Hospital ; Dennis Reginald Curnock, Charing Cross and Royal Dental Hospitals ; Arthur Cyril Dean, Guy's Hospital ; Eric Sutton Dickin, Liverpool University and National Dental Hospital ; William Edwin Dodd, Harold Mayston Fisher, and Charlie Lewis Hicks, Middlesex and Royal Dental Hospitals ; Walter Owen Hughes, Liverpool University ; Philip Everard Jessop and William George Lloyd, Guy's Hospital ; Arthur Helmuth John Miller, Charing Cross and Royal Dental Hospitals ; Thomas Dickson Muirhead, Lancelot Eric Charles Peckover, and Arthur George Drake Pridham, Middlesex and Royal Dental Hospitals ; Sydney Victor Shrimpton, Bristol University and Royal Dental Hospital ; Frederick Elliott Smith, Middlesex and National Dental Hospitals ; Donald Thorne, Charing Cross and Royal Dental Hospitals ; Vernon John Thurston and Clement John Lethbridge Wells, Middlesex and Royal Dental Hospitals ; Frank Edward Welton, Guy's Hospital ; Clarence Leslie Brunel White, Middlesex and Royal Dental Hospitals ; William Thomas Williams, Liverpool University ; Edgar Joseph Winstanley, Middlesex and Royal Dental Hospitals ; Samuel Anthony Withers, Guy's Hospital ; and Francis Bernard Yonge, Middlesex and Royal Dental Hospitals.

Dublin University : School of Physic, Trinity College.—At examinations held recently the following candidates were successful :—

Preliminary Scientific Medical Examination.

Botany and Zoology.—Mary Christina Sheppard, William Arthur Clarence Dowse, John Howard Blackwood Murphy, Henry Maxwell, Johannes Tobias Mynhardt, George Malone, and Jessie Gilbert.

Chemistry and Physics.—Eric James Lyndon, Mary Christina Sheppard, Alfred John Beckett, William Bruce Briggs, William Leech Young, Percival Atkin Dormer, Eric Stuart Ewing Mack, William Sweetman, Herbert William McAuliffe, Kenneth McGregor Greer, Frederick William Godbey and Henry Maxwell (equal), Jason Grant Bird, Lionel Wigoder, and James John Griffin, William Alfred Shannon, and Crawford Low Wilson (equal).

Intermediate Medical Examination, Part I.

Anatomy and Institutes of Medicine.—Joseph Roland Brennan, Patrick Rocks, Joseph Godfrey Bird, Henry James Rice, Paul Herbert Shelley Smith, David Shields Prentice, Marie Annette Hadden, William Frederick Wicht, Hirsh Brill, Thomas Hugh Robinson McKiernan, Philip Augustus Hall, Rita Henry, Millicent Hamilton-Johnstone, and Robert William Pritchard.

Intermediate Medical Examination, Part II.

Anatomy and Physiology.—Thomas Paul Chapman, Charles Lewers McDonogh, James Benjamin Taylor, Louis Blumberg, and Edward Lipman.

Final Medical Examination, Part I.

Materia Medica, Medical Jurisprudence and Hygiene, and Pathology.—Esther Violet Adderly, Charles Henry Comerford, Joseph Henry Cranston Walker, Frank Healy, Cecil Francis Brady, Mortimer McGee Russell, George William Doran, Thomas Edward Bellingham Beatty (medical jurisprudence and hygiene, pathology), William Hunt (medical jurisprudence and hygiene, pathology), John Armstrong Crozier Kidd (medical jurisprudence and hygiene, pathology), Thomas William Sweetman (materia medica, pathology), Leyburne Murphy (medical jurisprudence and hygiene, materia medica), and James Edward Jameson (pathology, completing examination).

Final Medical Examination, Part II.

Surgery.—Frederick Harris, George Brownrigg Hadden, Edward Percival H. Vickery, Geoffrey Arthur Hoffman, Eric Alfred Lumley, Edward Llewellyn Foot Nash, David Stanley Martin, Edward Gordon Fish, Hilda Maud Marsh, and Edmond Robinson.

Medicine.—Eric Alfred Lumley, Frederick Harris, Walter Joseph Ronan, Edward Percival Hadden Vickery, Bertrand Cecil Owens Sheridan, Francis Albert L'Estrange, Amos George Varian, Robert Alexander Anderson, George Brownrigg Hadden, Kathleen Dorathea Wallace, Joseph Patrick Quinn, Robert William Chapman, Frederick Robert Dougan, David Stanley Martin, and Thomas James Logan Thompson.

Midwifery.—Isaac Whitla Corkey (high marks), Edmund Duncan Tranchell Hayes, Eric William Craig, Richard Wellington Shegog, Violet Mabel Deale, Eugene John McSwiney, Herrbert Mitchell, Douglas Chetham Pim, Geraldine Murphy, Hilda Maud Marsh, George Stanton, Herbert Daniel, Christopher Charles Albertyn, Edward Mannix, Andrew William Palethorp Todd, Sydney Walter Fisher, Francis Joseph Ord King, Maurice Baylis King, David Henry Hall, Cecil McLaren West, Joseph Henry Cranston Walker, Alfred William Darnley Magee, Arthur Cyril Bateman, George Joughin, Audrew John Horne, and David Stanley Martin.

Final Dental Examination (B. Dent. Sc.).

Herbert Wright.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Cormac, H. Dove, M.B., M.S. Madras, has been appointed Medical Superintendent of the Cheshire County Asylum, Parkside Macclesfield.

Davies-Colley, Eleanor, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Surgical Registrar to the Royal Free Hospital.

Gunning, R. C., Lieutenant-Colonel, R.A.M.C. (retired), has been appointed by the War Office Commandant of the American Women's War Relief Fund Hospital at Paignton (Devon).

Johnston, T. B., M.B., Ch.B. Edin., has been appointed Lecturer and Demonstrator in Anatomy at University College, London.

Kelly, John B., L.R.C.P. & S. Irel., has been appointed Temporary Medical Officer for the Bleadon District by the Axbridge (Somerset) Board of Guardians.

Lowry, Eleanor, M.B., B.S. Lond., has been appointed Clinical Assistant to the Throat, Nose, and Ear Department of the Royal Free Hospital.

Martin, Douglas, M.B., Ch.B. Edin., has been appointed School Medical Officer and Assistant Medical Officer of Health to the Borough of South Shields.

O'Donovan, W. J., M.D. Lond., M.R.C.P. Lond., has been appointed Acting Assistant Physician to the Royal Free Hospital.

Pickard, Ellen M., M.D., B.S. Lond., has been appointed Medical Registrar to the Royal Free Hospital.

Price, Frederick W., M.D. Edin., M.R.C.P. Lond., has been appointed Honorary Assistant Physician to the National Hospital for Diseases of the Heart.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ashton-under-Lyne Union Workhouse.—Resident Assistant Medical Officer. Salary £150 per annum, with rations, laundry, and residence.

Barnsley, Beckett Hospital and Dispensary.—Second House Surgeon, unmarried. Salary £100 per annum, with apartments, board, and laundry.

Barrow-in-Furness, North Lonsdale Hospital.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.

Bedford County Hospital.—Assistant House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and laundry.

Bethnal Green Infirmary, Cambridge-road, N.E.—Assistant Medical Officer. Salary at rate of £200 per annum, with apartments, board, and washing.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birmingham City Mental Hospital, Rubery-hill.—Female Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.

Sunderland Royal Infirmary.—Senior Resident Medical Officer and Two Junior House Surgeons. Salaries £150 and £120 per annum respectively, with board, residence, and laundry.

Swansea General and Eye Hospital.—House Surgeon. Salary £125 per annum, with board, washing, and attendance.

Taunton, Somerset and Bath Asylum, Cotford.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, washing, attendance, &c.

Taunton, Taunton and Somerset Hospital.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.

Trinidad Lunatic Asylum.—Assistant Medical Superintendent. Salary £250 per annum, £80 ration allowance, bachelor's quarters.

Truro, Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £150 per annum, with rooms, board, and washing.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, &c.

University of London.—Examiners.

Wakefield, Clayton Hospital.—Senior House Surgeon. Salary £160 per annum, with board, lodging, and laundry.

Wakefield, West Riding Asylum.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, washing, and attendance.

Walsall and District Hospital.—Junior House Surgeon and Anæsthetist. Salary £110 per annum, with board, residence, and laundry.

Warrington Infirmary and Dispensary.—Senior House Surgeon. Salary at rate of £200 per annum, with board, apartments, and laundry.

West Bromwich and District Hospital.—House Surgeon and Assistant House Surgeon. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

West Ham County Borough.—Assistant School Medical Officer. Salary £300 per annum.

West Ham Union.—Infirmary, Whipps Cross-road, Leytonstone, N.E.: Second Assistant Resident Medical Officer. Salary £250 per annum, with usual residential allowances. Sick Home, 95, Forest-lane, Forest Gate, E.: Deputy Medical Officer. Salary £250 per annum, with usual residential allowances.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Senior House Surgeon. Salary £170 per annum, with board, apartments, and washing. Also Female Junior House Surgeon. Salary £130 per annum, with board, apartments, and washing.

Wilts County Council General Education Committee.—Temporary Assistant School Medical Inspector. Salary at rate of £300 per annum, with travelling and maintenance allowances.

Worcester General Infirmary.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing.

Worksop Victoria Hospital and Dispensary.—Medical Officer and House Surgeon. Salary £150 per annum, with rooms, coal, light, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Hamilton, in the county of Lanarkshire, and at Rathfriland, in County Down.

Births, Marriages, and Deaths.

BIRTHS.

Baldwin.—On Dec. 7th, at Manchester-square, W., the wife of Aslett Baldwin, F.R.C.S., of a son.

Evans.—On Dec. 7th, at Church-street, Kidderminster, the wife of O. C. Penrhys Evans, M.D., of a daughter.

Sambon.—On Dec. 10th, at Woodlawn, Shoot-up Hill, N.W., the wife of Louis Westenra Sambon, of a son.

MARRIAGES.

Colbatch Clark—Dudding.—On Dec. 10th, at St. Lawrence's Church, Canon Pyon, Herefordshire, Henry Colbatch Clark, M.R.C.S., L.R.C.P., of Wellington, Hereford, to Florence Mary, eldest daughter of the late Frederick Walter Dudding and Mrs. Dudding, of Bayham House, Ipswich.

Simpson—Bedell-Sivright.—On Dec. 12th, at St. Paul's Church, Sheerness, Alexander Simpson, Surgeon, Royal Navy, to Catherine, second daughter of W. H. R. Bedell-Sivright, of Southouse, Mid-Lothian.

DEATHS.

Harris.—On Dec. 11th, at Shanklin, Deputy Surgeon-General William Henry Harris, late I.M.S. of Madras, in his 85th year.

Moreton.—On Dec. 5th, at Earlscroft, Tarvin, Cheshire, James Earl Moreton, F.R.C.S., aged 83 years.

Pitts.—On Dec. 13th, after a long illness, Bernard Pitts, M.A., M.C. Cantab., F.R.C.S. Eng., Consulting Surgeon to St. Thomas's Hospital and to the Hospital for Children, Great Ormond-street, aged 66 years.

Turner.—On Dec. 9th, at "Holmwood," Bournemouth, Henry Gunton Turner, M.R.C.S., aged 68 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND SANITATION IN JAMAICA.

Sir William Henry Manning, K.C.M.G., C.B., Governor of Jamaica, in his report on the colony for the year 1913–14, just presented to Parliament, devotes considerable space to matters concerning health and sanitation. He estimates the present population of the colony at 864,864, but there is always a good deal of migration going on; and the statistics of marriages, births, and deaths are calculated on the mean island population for the year, which in 1913 was 863,427. The marriage-rate per 1000 was 3·1, the birth-rate 35·3, and the death-rate 21·7. Of the births 64·5 per 100 were illegitimate, as compared with 63·3 per cent. for the decade. The general death-rate showed a decrease of 3·4 per 1000, and the proportion due to deaths of infants under 5 years of age showed a reduction of 4·3 per cent. There was great variation in both the birth- and death-rates in different parts of the island.

Deaths from malaria in Kingston numbered 22, as against 25 in the previous year, and from fever (not otherwise defined) 21, against 29. There was no vote for the abatement of malaria during the year, and the Commission was dissolved, leaving the works contemplated not quite complete. It is satisfactory to note that the position reached in 1912–13 has been maintained, and that there has been a further slight decrease in the number of victims from this malady. It must, however, be recollected that until measures for abatement of malaria are universal throughout the island the disease cannot be wholly eliminated from the statistics of Kingston, as the general penitentiary, the lunatic asylum, the public hospital, and other institutions draw their inmates from all parts of the colony, and many persons come from the country for medical advice and treatment. Emigrants returning from the malarious portions of Central America also contribute materially to the number of cases.

Salvarsan was utilised in the treatment of yaws and syphilis in the public general hospitals in 778 cases, and in 90 at out-stations, the patients returning to their homes after the operation on these last-mentioned occasions. One death occurred in hospital, and 46 patients remained under treatment, while all the others are reported to have had their symptoms cured. Reports have also been received of 40 cases treated in the Kingston and St. Andrew Poor-house, and 14 in the St. Ann Poor-house. One patient died 21 days after a second injection, and one 73 days after the first (but unfortunately no post-mortem examination was made in either case and the causes of the deaths have not been ascertained), and one remained under treatment, the remainder having their symptoms cured or much improved. Some of these cases were of 7 to 10 years' duration, and apparently hopeless under the treatment formerly resorted to, the patients lapsing into pauperism and becoming inmates of the poor-houses. Nearly all of them had a complete recovery and several were able to return to work. This remedy promises under proper safeguards to solve the problem of preventing the ravages due to yaws and syphilis. There were 11,945 attendances on yaws patients without salvarsan treatment, 6272 being first visits. The deaths registered as due to yaws and syphilis during the year numbered 244.

A special feature of the medical returns is the decrease of 2347 in the number of cases of malaria treated in the hospitals and of 25 in the mortality from that disease as compared with the previous year. The Registrar-General's return shows a decrease of 168 in the total number of deaths in the island attributed to malaria, equal to 31·21 per cent. Eighty of the deaths are not medically certified, but as the percentage of decreases shows so near an approximation to the hospital cases the figures may be regarded as substantially accurate. The superintending medical officer has submitted no comments on these figures, but he has furnished reports by various district medical officers showing in most cases that some attention is being paid to the question of mosquito reduction by the local health authorities. It is understood that the late Malaria Commission, acting as they believed on the theory and practice which has proved effective elsewhere, endeavoured to abate the breeding of malarial mosquitoes and to diminish the sources whence the reduced number of mosquitoes could become infected, thus rendering as many as possible harmless as transmitters of the disease.

The number of persons thymolised for hook-worm during the year was 8204.

The total number of patients treated in the public general hospitals during the year was 30,716, and the number of deaths in hospitals was 617. Of the latter, 54 were due to malarial fever, 5 to skin diseases, 91 to diseases of the digestive system, 30 to local injuries, 45 to diseases of the respiratory system, 38 to diseases of the circulatory system, 7 to diseases of the cellular tissue, 17 to ankylostomiasis, 15 to syphilis, 16 to anæmia, and 1 to blackwater fever.

Dr. Seidelin, of the Liverpool School of Tropical Medicine, paid a visit to the island for the purpose of investigating "vomiting sickness," and Dr. Scott, the Government bacteriologist, was associated with him in so far that he assisted him in certain portions of his work, the Government laboratory being placed at his disposal. By the process of eliminating cases, loosely termed "vomiting sickness," which were traceable to specific causes, and grouping the remainder which showed similar characteristics, it was hoped that the disease would be recognised, but the results have been negative. The theory of yellow fever has been exploded, and Dr. Scott advances the suggestion that "the rapidity of progress (or, in rarer instances, rapid and complete recovery) rather indicates the action of a poison," adding that "since feeding experiments have proved negative, and chemical tests (which in former years have been repeatedly tried by the island chemist) have revealed none of the usual poisons, and no signs of alkaloids, the poison (if such it be) is one which rapidly leaves the stomach or is rapidly decomposed: for example, it may be of the nature of a glucoside," and "the only suggestion I can offer as to the source of this hypothetical poison is that, since one can never obtain any history to implicate any particular article of food, it is due to something which is apparently dangerous only at certain times of the year, some fruit, perhaps, or vegetables, or, what in my opinion is more probable, some growth (fungus, yeast, moulds, &c.) on or in this food, rendering it toxic."

Dr. L. Sambon also visited the island, accompanied by Captain Siler, M.D., of the United States army, to make investigation into the prevalence of pellagra, and the Government bacteriological staff is continuing the investigation.

The Central Board of Health has given much attention to questions of public health, especially in connexion with measures for the prevention of plague, for the destruction of the hook-worm, for the avoidance of infection from consumption, &c. Certain leaflets prepared or obtained by them have been widely circulated, and the local health authorities are now in possession of regulations embracing a wide range of duties bearing on the prevention of diseases, the notification of infectious diseases, &c. Some system is gradually being infused into the operations of the local health authorities, and as these become more efficient it may be confidently expected that the health of the population will improve.

The Lepers' Home had 111 patients on March 31st, 1913. There were admitted during the year 22; 4 were discharged, 1 absconded, 8 died, leaving on March 31st, 1914, 120. The death-rate was 6 per cent. The medical superintendent reports that he has abandoned the treatment by nastin after a fair trial, and that he has been using "antileprol" for over two years with very excellent and gratifying results. He explains that "antileprol" is a refined product of chaulmoogra oil.

OFFICIAL MANNERS.

WE are asked by the clerk of the Ilford urban district council to state that the postcard, which was reproduced under the above heading in this column last week, was despatched, through the inadvertence of a temporary clerk, in mistake for another printed form of rejection intended to be sent in a closed envelope to unsuccessful applicants for appointments under the council. We understand that each applicant who received one of the offending postcards has now been written to to this effect, with an expression of regret for the error.

CEREBRO-SPINAL MENINGITIS IN CRETE.

Mr. E. C. D. Rawlins, His Majesty's Vice-Consul in Crete, in a recent report to the Foreign Office, writes: "The years 1912-13 have been noticeable for outbreaks of cerebro-spinal meningitis and, towards the end of the latter year, small-pox. The meningitis outbreak at one time assumed serious proportions, but the authorities took energetic action and the disease gradually died down. It appears, though, that it has become nearly endemic in the Candia district, and some cases are always to be found there. Candia seems to be peculiarly unhealthy, much more so than the towns of Canea and Rethymo, and this state of affairs is said to be due to the unsatisfactory water-supply in the former town. On the whole, however, it may be said that the island of Crete enjoys a most salubrious climate. The total population of the island at the last census was 336,151, that of the three principal towns being—Canea, 24,399; Candia, 25,185; and Rethymo, 9086."

PERKINS'S TRACTORS.

To the Editor of THE LANCET.

SIR,—Respecting these tractors, which have received interesting notices in THE LANCET of Sept. 12th (p. 728) and Oct. 10th (p. 928) last, I remember that Lord Byron's "English Bards and Scotch Reviewers" has a reference to them:—

> "The cow-pox, tractors, galvanism, and gas,
> In turns appear, to make the vulgar stare,
> Till the swoln bubble bursts—and all is air."

Quite true—as far as the tractors are concerned!

I am, Sir, yours faithfully,
Santiago, Chili, Nov. 16th, 1914. H. BOSHOUWERS.

KING ALBERT'S BOOK.

THIS handsome book,[1] published this week, is a worthy expression of world-wide tribute to the outstanding man and outstanding nation of an epoch. It contains 238 contributions in speech or song, music or picture from royalties and other potentates, diplomatists and statesmen, professors, artists, men and women of letters, ecclesiastics, scientists and medical men, of various nationalities. The editor, Mr. Hall Caine, contributes an introduction, and an excellent portrait of King Albert in uniform constitutes the frontispiece. The book is admirably bound and the work of the publishers cannot be too highly praised. The entire proceeds are to be devoted to the *Daily Telegraph* Belgian Fund. Many a waiting-room table will surely be enriched by its presence.

SUNSHINE AND STRAWBERRIES AT SALCOMBE.

A CORRESPONDENT writing from Salcombe, South Devon, states: "Last week (I am writing on Nov. 23rd) I had on my table peas, French beans, globe artichokes, tomatoes, and strawberries fresh from my garden, and grown without any special attention at all. The strawberries have been our chief dessert for more than six weeks now, although the same plants gave us a splendid crop in June. To-day roses are flowering gaily, and one can scarcely realise the awful weather experienced north. Those fortunate enough to live in the houses sheltered from the north-east enjoy a warm and sunny environment. Last winter we found an aloe in full flower and bunches of subtropical flowers were gathered." All this within five hours' journey of London should sound attractive to those needing real rest in these troublous and strenuous times.

ROYAL METEOROLOGICAL SOCIETY.

AT a meeting of the Royal Meteorological Society held on Dec. 16th at the Surveyors' Institution, Westminster, a paper was read by Mr. A. E. M. Geddes, M.A., entitled "Observations of the Upper Atmosphere at Aberdeen by Means of Pilot Balloons." The observations were made at the Observatory, King's College, during the years 1912 and 1913, and in every case two theodolites were used, thus securing an accurate determination of the flights to a level of 3000 metres. In clear weather the upward velocity of the balloon was shown to be fairly uniform, but to depend on more than the free lift. When clouds are present they influence considerably this velocity, the effect differing according to the nature of the cloud. The gradient wind velocities and directions have been calculated and a useful comparison made with those actually found by observation.

A SERVICE MATCH-BOX COVER.

Messrs. Bryant and May, of Fairfield Works, Bow, London, E., have just introduced a metal match-box cover designed for the use of officers and men in the Expeditionary Force. The cover affords protection to the matches and rubber against wet. Its shape resembles a miniature coal-scuttle, with a hinge and pin at one of the corners. The device will no doubt be appreciated.

BARNET X RAY PLATES.

WE have received from Messrs. Elliott and Sons, Limited, samples of the Barnet X Ray Plates, which have been exclusively prepared for radiographic purposes. They are rich in silver, and we have found it easy to obtain good results with exposures rather less than usual. They seem sensitive to the fluorescence of the intensifying screen, and should become popular for this purpose. Development is the same as for other plates, and they appear to give equally good results with any of the developing agents in ordinary use. We note that a useful size for taking radiographs of the long bones has been introduced—10 in. × 6 in.—which effects a saving over the usual 10 in. × 8 in., the extra 2 inches width of the latter representing so much waste in a large proportion of the exposures made.

---

[1] London: Hodder and Stoughton. Pp. 188. Price 3s.

WE have received from the publisher, Mr. T. Askew Miller, of Capetown, a useful little pamphlet on the House Fly, a Carrier of Disease and Death, compiled by Mr. F. W. Fitzsimons, F.Z.S., of Port Elizabeth Museum. The first edition of 10,000 copies has been distributed free amongst the columns of the South African forces in the field, with a view to enlisting the active coöperation of the men in the destruction of flies as the carriers of typhoid and other diseases. The pamphlet describes in simple terms the life history and habits of the fly, and the importance of conscientious attention to the carrying out of sanitary measures is thus enforced.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Croonian Lectures

ON

MODERN ASPECTS OF CERTAIN PROBLEMS IN THE PATHOLOGY OF MENTAL DISORDERS.

Delivered before the Royal College of Physicians of London,

By EDWIN GOODALL, M.D. Lond., B.S.,
F.R.C.P. Lond.,
MEDICAL SUPERINTENDENT, CITY OF CARDIFF MENTAL HOSPITAL.

LECTURE IV.*

Sir Thomas Barlow and Gentlemen,—I propose in this lecture to lay before you the experience which has been gained and the information which has accrued from the application of the method of complement deviation, and from the study of the cerebro-spinal fluid in psychiatry. Since 1909 I have, in conjunction with my colleagues, and more especially with Dr. H. A. Schölberg, of Cardiff, given systematic attention to these matters, we having had at our disposal abundant material in the wards of the Cardiff Mental Hospital, controlled by concurrent observations upon patients from the Cardiff Infirmary and private practice. Throughout the period of our observations I have made regular reference to the current literature, with a view to comparison.

The Wassermann Reaction.

In the *Journal of Mental Science* for April, 1911, Schölberg and I published an account of our observations upon the Wassermann reaction in 172 cases of insanity of all kinds, and upon 66 control cases, syphilitic and other, not insane. This article contained full references to the work that had been done up to that date. The observations have been systematically carried on, and a brief account of them was given by us at the last International Congress of Medicine. In respect to the complement-deviation test in cases of dementia paralytica I am disposed to think that medical men not engaged in the domain of mental disorders, and even many so engaged, are under the belief that this is a *chose jugée*, and that in general paralysis the Wassermann test is positive in 100 per cent. of the cases, whether in the serum or the cerebro-spinal fluid. The observations which follow will show that the matter is not so simple and definite as this. Table XX. embodies, to the best of my knowledge, all the important observations upon the frequency of a positive reaction in the serum and cerebro-spinal fluid from 1907 to 1913 inclusive, though some it has been necessary to omit for the curious reason that the authors have omitted to state which of the two fluids in question they worked with.

An examination of Table XX. shows that the results obtained by the numerous observers cited are by no means uniform and by no means in accord with the belief to which I have referred, even such as are quite recent. Schölberg and I, in our first series of observations, worked with 0·1 c.c. of the reagents of the test, the patient's amboceptor being used in a solution of 1 in 10; and as antigen we employed, in common with a large number of other workers, some, at any rate, of whom obtained a high percentage of positive results, alcoholic solution of guinea-pig's heart. Our percentage of positive results with the serum

* Lectures I., II., and III. were published in The Lancet of Dec. 5th (p. 1287), 12th (p. 1343), and 19th (p. [illegible]), 1914, respectively.

No. 4765.

in dementia paralytica (49 cases) was 75·50; retardation of hæmolysis occurred in 6·12 per cent. And here I would state that throughout our observations, over the whole period of time, from 1909 to 1913 inclusive, we employed at each sitting a known case of syphilis and a known non-syphilitic as controls to the cases of insanity, so that whatever the result was with the serum of the insane (whether general paralytics or other) typical results were obtained with the two controls. A series of cases of syphilis, numbering 38, of whom nearly four-fifths were in the tertiary stage, were tested precisely in the same way as the general paralytics; the serum of these yielded 89·47 per cent. of positive results with the serum.

As regards the cerebro-spinal fluid, in this first series 41 cases gave positive results in 41·46 per cent. and retardation of hæmolysis in 9·75 per cent. In our further observations we employed as antigen alcoholic extract of congenital luetic liver, and for a time continued to use 0·1 c.c. of the reagents of the test, so that the total number of sera examined in this way reached 67 and of cerebro-spinal fluids 60. A positive Wassermann resulted in 67·16 per cent. in the serum, with retardation of hæmolysis in 7·46 per cent. and a negative reaction in 23·88 per cent.; in the cerebro-spinal fluid these figures were 36·66 per cent. and 13·33 per cent. and 48·33 per cent., so that our percentage of positive results was still less with the larger number of observations and in both fluids. In all observations thereafter not less than 0·2 c.c. of the various reagents of the test have been used with a view to diminishing experimental error. The total number of sera (dementia paralytica) examined in this way was 39 and of cerebro-spinal fluids the same. With the serum the results were positive Wassermann in 56·41 per cent., negative in 25·64 per cent., and retarded hæmolysis occurred in 17·94 per cent. With the cerebro-spinal fluid: positive Wassermann in 30·77 per cent., negative in 48·71 per cent., and retarded hæmolysis in 20·51 per cent. So that the percentage of positive results was still further reduced in this last series, both as regards the serum and the cerebro-spinal fluid.

The number of cases in which a merely retarded hæmolysis was recorded in both fluids is a feature. Only those cases were recorded as positive where the blood corpuscles were completely deposited, leaving a water-like supernatant fluid. It is to be observed that very few authors indeed make mention of cases of retarded hæmolysis. I have pointed out in Table XX. that Bundschuh, who in 1913 gave results in respect of 71 cases, obtaining 100 per cent. of positive reactions in both fluids, states that these cases include instances of deviations of various degrees. Candler observes that Plaut has stated that he has met with all grades of positive reactions with the fluids in general paralysis. Candler himself has had cases in which the reaction was quite slight. In the absence of a definite statement to the effect that results are classified in three categories (hæmolysis completely absent, complete, and retarded) one takes leave to doubt the accuracy of a great number of recorded results. All the fluids used in our observations were thoroughly centrifugalised before inactivation; I have only found two references to this point, one by Klieneberger, who centrifugalised all the cerebro-spinal fluids in his observations, the other by Nabarro, who only centrifugalised when the cerebro-spinal fluid contained blood. Quite recently von Wassermann and Lange[1] have shown that the lymphocytes are the source of the Wassermann reaction in the cerebro-spinal fluid. The centrifugalisation of the fluid in our cases, with the use of the supernatant fluid, will therefore go towards accounting for our low percentage of positive results. And the importance of stating whether or not the fluid was centrifugalised is enhanced by these observations. There is further noticeable about the published work a singular absence of statement as to the stage of the malady and the mental and physical conditions of the patient at the date of the test. The general paralytics with whom the observations here recorded are concerned, 106 in number, were, with some six exceptions, advanced in the disease at the date of examination; in all, with these exceptions, the disease was well over a year old, and very frequently over two years old. The great majority were considerably reduced physically, and exhibited various degrees of dementia. These cases were therefore, with few exceptions, in the late second or in the third stage of the disease. In any future record of the results of the complement-deviation test in dementia paralytica it appears to me essential that cases should be placed in groups, according to duration and to clinical aspect (whether fulminating, progressive, quiescent, or in actual remission, or near the end of the malady, or in or recovering from seizures). Statistics should be based upon some such grouping. I may in passing comment upon the extreme paucity of records of the results of the test in the earliest stage of the disease (dementia paralytica), in which it would be seen by experienced general practitioners and consultants. Plaut[2] states that the Wassermann reaction is positive in the earliest stages both in the serum and cerebro-spinal fluid, but I find no statistical evidence on the point.

Variability of the Wassermann Reaction in Dementia Paralytica.

Considerable experience enables me to deal with the point of the constancy or otherwise of the reaction in different phases or aspects of this disease, and, in respect to the roughly divisible, classical stages, in the second and third stages. I would first review briefly the statements made by various authors concerning this point. As regards the applicability of the complement-deviation test in the very earliest stage of the disease, Plaut[3] has stated that the reaction is present in its very earliest stage; in this he is supported by others; thus, Rossi,[3] Boas and Neve,[3] Bundschuh,[4] Klieneberger,[5] Zingerle.[6] According to some of these authors a positive Wassermann is obtainable in the serum and cerebro-spinal fluid before a clinical diagnosis can be made. The variability of the reaction in both fluids at different periods of the disease in the same individual, without, however, definite correlation between nature or strength of reaction and phase or degree of severity of the disease, is referred to by several writers: thus, Marinesco,[3] Kafka,[3] Boas and Neve,[3] Plaut,[3] Rossi,[3] Hübner and Hallarger,[3] Raviart, Breton, and Petit,[3] Wassermeyer and Bering,[3] Bundschuh,[4] Nabarro,[7] Eyman and O'Brien,[8] and Candler.[9] It may be affirmed that the consensus of opinion is against any correlation of the kind referred to. Some writers have, however, recorded instances of a feeble or negative Wassermann reaction in both fluids in stationary conditions, or where the disease was progressing slowly, or tending towards remission; thus, Plaut,[3] Obregia and Bruckner,[3] Neue,[10] and Schoenhals.[11] It has also been observed that cases which give a negative Wassermann often show clinical peculiarities (thus, von Roesen[12]). Statements as to the behaviour of the test during remissions appear to be exceedingly rare; I am able to find only two of any importance, one by Kafka,[3] according to which five such instances gave a positive reaction, and this author considers that remissions do not affect the reaction unless they are of a very marked kind. The other statement is by Bundschuh,[4] who also obtained a positive reaction and in four marked instances. The existence of cases of dementia paralytica in which the test is negative in both fluids over long periods I find recognised by Kafka,[3] Binswanger[13] (who used large amounts of amboceptor), Neue[10] (his were not stationary cases), Nabarro.[7] The last named employed increasing amounts of patient's amboceptor, and is unable to agree with the statement of well-known writers that a negative reaction in the cerebro-spinal fluid is unusual.

From the foregoing statements and from a survey of the literature, it has to be recognised that the

Wassermann reaction may be negative at a given test in both the serum and cerebro-spinal fluid in clinically certain cases of dementia paralytica, and when the ordinary amount of the patient's amboceptor is employed. I am aware of the assertion as to the feasibility of converting a negative into a positive reaction by increasing the amount of this constituent of the test, and propose to deal with the point shortly. One may, however, point out that this assertion is based as yet on far too little published evidence. The reaction is negative in pronounced cases from time to time in the course of the case; in stationary conditions it is very often negative. (See Zaloziecki,[14] Schönhals.)[11]

I now submit to you extracts from a table exhibiting instances from my experience of the points referred to above. (Table XXI.) Some of these cases show that the important point of the repetition of the test has been attended to; this is one of the points on which extremely little precise information exists. In the course of these particular observations 99 cases of dementia paralytica were examined, but in these 226 examinations were made. I may draw your attention to certain features in these cases, leaving for the moment those connected with remissions, and the results of the use of increasing amount of amboceptor.

No. 1 (this case not reproduced) shows variations in the serum and cerebro-spinal fluid reactions without clinical change; also a tendency to a negative Wassermann as the disease becomes stationary or quiescent. No. 2, after more than four years of the disease, the patient being very advanced in it, negative reactions in both fluids, even with large amounts of amboceptor. No 7, two days after a slight exacerbation (local spasms), negative reactions in both fluids, with high amounts of amboceptor. Varying reactions in the serum without clinical change (30/9/13, 16/12/13, and 10/2/14). Retarded and positive reactions, disease stationary. No. 8, in florid state, very acute symptoms; negative reaction in serum, also in cerebro-spinal fluid with ordinary amount of amboceptor. Disease process milder; reaction in serum retarded or positive. In last stage, disease 3 years' duration; anomalous reactions. No. 12, negative reactions in both fluids in considerable amounts; patient in convulsions when examined. No. 16, advanced in disease, reactions negative with considerable amounts of both fluids. Since the above table was compiled another marked instance of lack of correlation occurred under my care, the case being that of a patient in an advanced stage of the disease, bedridden; with the serum, Wassermann was positive with 0·2 c.c. of a 1 in 5 dilution; at the same time negative with the cerebro-spinal fluid with the same strength and also with 0·2 c.c. and 1 c.c. of the pure fluid.

The relationship between the reaction and states of remission is illustrated by the following cases. No. 2. The reaction is seen to be positive sometimes in remission in both fluids. No. 3 (not reproduced). Positive and negative in the cerebro-spinal fluid. No. 6. Reactions retarded and positive in both fluids. No. 7. Reaction negative in the serum, positive in the cerebro-spinal fluid. No. 8. Reaction now positive, now negative in both fluids. No. 9. Reaction positive in both fluids. No. 13. Reactions negative in boths fluids, but once positive in cerebro-spinal fluid pure and in large amount. No. 14. Reactions negative in both fluids. And another case of marked remission, since the table was compiled: W + with 0·2 c.c. of pure cerebro-spinal fluid. From these observations it appears that there is no correlation between the reaction and a state of remission, a positive reaction being obtained in this state as often as a negative; and the reaction varying in a given case. This is in accord with the lack of correlation observed in other phases of the disease. Nevertheless, in respect to remissions as well as to the very earliest stage of dementia paralytica, more observations are needed; and especially in respect of those very pronounced remissions in which the patient is well enough to have his liberty and carry on his occupation.

If I may here diverge from my course a moment I would call your attention to the fact that there are cases of dementia paralytica in which the recovery from the morbid manifestations is so marked, and especially so long-lasting, that the expression "remission" is far too weak to apply to them. Rather should we speak, with Petrazzini,[15] of a "cure with defect." This writer describes a well-observed case of the disease of 23 years' standing, in which a remission occurred in the fourth year, and thereafter the patient's condition remained such that it is best described by the expression employed above, and for 19 years. In this case the Wassermann test was positive on two occasions during the period of comparative health. Petrazzini has collected two series of cases from various authors; in the first, consisting of 25 cases, the disease lasted from 13 to 26 years, in one 32 years. In the second series there are cases lasting from 9 to 25 years. Spirochætæ have been shown by Neisser to live for a great many years in gummata, and in the lesions of dementia paralytica they may persist, perhaps indefinitely, in a resting form, becoming from time to time active again.

Results of Increasing the Patient's Amboceptor (Serum and Cerebro-spinal Fluid) in the Complement-deviation Test in Mental Disorders.

Not long—probably from one to two years—after the first application of the Wassermann test in dementia paralytica the practice was advocated of employing a larger amount of the patient's cerebro-spinal fluid where a negative result had been obtained with the usual amount. In our article published in 1911, already referred to, Schölberg and I mentioned the statement of Boas and Neve, the Danish observers, to the effect that, whereas they only obtained 52 per cent. of positive results in the cerebro-spinal fluid in dementia paralytica with 0·2 c.c. of the fluid, the percentage rose to 90 when they took double this amount. Of late years the statement has been made with considerable confidence that the failure to obtain a positive result with the cerebro-spinal fluid in this disease was due to the use of insufficient fluid. Extremely little evidence has been produced in support of this. Therefore Schölberg and I have for some two years tested this point. It is not surprising, perhaps, that evidence has been lacking, for if the Wassermann test as usually performed is laborious enough, how much more so its performance with three or four strengths of the patient's serum and cerebro-spinal fluid ? I would therefore venture to lay stress upon the results collected by my colleague and myself, as I am not aware that any similar ones have been published in respect of the psychoses. Table XXII. shows the results we obtained by increasing the patient's amboceptor, both serum and cerebro-spinal fluid, the other constituents of the test remaining constant. The results in dementia paralytica were controlled, as shown, by similar observations upon cases of other psychoses.

TABLE XXII.—*Results Obtained by Using Patients' Serum-Amboceptor in Increased Amount, the other Reagents of the Test Remaining Constant (0·2 c.c.).*

1.—*Dementia Paralytica.*

A Total + or ret. Results.	B Altered to r. or 0.	C Results in B altered to r. or 0.
0·2 c.c.	0·4 c.c.	0·6 c.c.
58	20	13
	Of which 13 altered to 0 = 22·4%.	Of which 8 altered to 0 = 13·8%.

0·2 c.c.	0·4 c.c.	0·6 c.c.
72	39	23
	Of which 18 altered to 0 = 25%.	Of which 17 altered to 0 = 23·6%.

By using up to 0·6 c.c. amboceptor additional positive Wassermann's = 48·6%.

2.—*Other Mental Disorders.*

A	B	C
73	11	10
	Of which 2 altered to 0 = nearly 3%.	Of which 3 altered to 0 = 4·1%.

By using up to 0·6 c.c. amboceptor additional positive Wassermann's = 7%.

The table shows that a negative Wassermann or a merely retarded hæmolysis with the usual amount (0·2 c.c.) of serum-amboceptor is converted into a positive Wassermann by taking up to 0·6 c.c. in 36 per cent. of cases of dementia paralytica and 5 to 6 per cent. of cases of other mental disorders. In the case of the cerebro-spinal fluid these figures are respectively 48·6 per cent. and 7 per cent. In both cases the conversion is some seven times more frequent in dementia paralytica. These results afford, therefore, justification for the recommendation that a larger amount of patient's amboceptor be taken in the former disease where negative or incomplete results are obtained with the usual amount. No doubt a larger experience is required (in order to which several observers are necessary), but it is apparent that the fluids of non-general paralytics in exceptional cases will give a positive reaction when unusual amounts are used. If now we consider the positive results obtained by Schölberg and myself in 39 cases of dementia paralytica with 0·2 c.c. amboceptor, which I have already stated, in the light of the information furnished by Table XXII., we find them modified as follows. In respect to the serum 36 per cent. of the 17 cases of negative Wassermann or merely retarded hæmolysis would have given a positive reaction had 0·6 c.c. amboceptor been taken, raising the percentage of cases of positive Wassermann with the serum from 56·41 to nearly 72 per cent. And with respect to the cerebro-spinal fluid 48·6 per cent. of the 27 cases of negative Wassermann or merely retarded hæmolysis would have given a positive reaction with the higher amount of amboceptor, raising the percentage of cases of positive Wassermann with the cerebro-spinal fluid from 30·7 per cent. to 64 per cent. These are very substantial increases: nevertheless, even with this fortification, our positive results fall considerably below those given by many writers. But I would emphasise the point that practically none of these states the amount of fluid which was worked with, nor the duration or degree of severity of the disease; in brief, the class of case. Furthermore, it is far from certain, as already intimated, that a rigid and uniform interpretation has been placed by various observers upon the expression "negative hæmolysis." I am interested to find that Muirhead and Nabarro (see Table XX.), who presumably worked with patients of much the same class as ours (and the former states that her cases were in all stages), at the Edinburgh and Wakefield Asylums, obtained 76·7 per cent. and 67 per cent. respectively of positive results in the serum and 71·4 per cent. and 70 per cent. respectively in the cerebro-spinal fluid—figures according well with those of Schölberg and myself, as estimated above. Since the above was written I have had the opportunity to work out the results actually obtained by us in the cerebro-spinal fluid with 0·6 c.c. of a dilution of 1 in 10 in a series of cases of dementia paralytica (76 tests) and of cases of other forms of insanity (72 tests), with no evidence of cerebro-spinal disease. The actual positive results obtained with 0·6 c.c. of 1 in 10 dilution in a series of examinations (respectively 68·42 per cent. and 6·94 per cent.) agree pretty well with those arrived at theoretically as explained above for dementia paralytica and later for non-general paralysis (respectively 64 per cent. and 8 per cent.).

Recent Observations on the Use of Increased Amounts of Amboceptor (Cerebro-spinal Fluid).

At this point it will be appropriate to bring before you the more recent statements respecting results obtainable by the method of detecting a complement-binding substance when in small amount in the cerebro-spinal fluid, that is, by using increased amounts of amboceptor, the "auswertungs methode" of German writers. About 1909 the teaching of the leading authorities, such as Plaut, was to the effect that a positive Wassermann in the cerebro-spinal fluid was obtained with the original method only in dementia paralytica, with the exception of rare cases of cerebro-spinal lues; the reaction was negative in other organic disease of the cerebro-spinal axis, and absent in syphilis when this axis was not involved. Nonne[16] in 1910 recorded the observation made by Hauptmann, working in his wards, to the effect that in lues cerebro-spinalis and in tabes, when the reaction was negative with the original method, a positive reaction was obtainable by using increased amounts of the fluid to be tested. Further researches in Nonne's wards have confirmed this observation. Hauptmann[17] later described his results in detail, and showed that in numerous controls, amongst which various non-syphilitic diseases of the nervous system figured, the negative Wassermann result was never converted into a positive by the procedure advocated. The reaction remained negative in such cases even when the patient had had syphilis. Whereas with 0·2 c.c. of the amboceptor fluid over 90 per cent. of cases of cerebro-spinal lues give, according to Hauptmann, a negative Wassermann, the result is usually positive with 0·4 to 1 c.c. Klieneberger[18] bears out Hauptmann's results, and points out further that the same results are obtained by reducing the amount of complement used instead of increasing the amount of cerebro-spinal fluid. Kafka[19] also confirms these results. In two cases of disseminated sclerosis, however, Eichelberg[20] obtained a positive reaction by using 0·6 c.c. of the cerebro-spinal fluid. Gruetter,[21] writing in 1913, observes that the "auswertungs methode" has increased the number of positive results in dementia paralytica. but less in this than in what he terms "metasyphilitic" diseases of the nervous system. Fraenkel,[21] who corroborates Hauptmann's work, states that by taking up to 1 c.c. of (apparently) pure cerebro-spinal fluid 96 per cent. of positive results are obtained in cases of cerebro-spinal lues. If these observations are borne out it will be necessary to make the test with this quantity before a diagnosis can be made. It is extraordinary that so few cases of cerebral lues, whether local or diffuse, give a positive reaction with small amounts of cerebro-spinal fluid as compared with cases of dementia paralytica. If it is assumed that in the latter disease the spirochæta is in an active and fully-developed condition it is remarkable that its demonstration in the cortex cerebri should be so difficult with the methods in vogue.

But to proceed: the early teaching seems in danger of direct contradiction as a result of recent work, which is to the effect that a positive reaction is obtained in the cerebro-spinal fluid in florid syphilis, without affection of the cerebro-spinal system (without evidence of such, that is). Thus, Gruetter refers to the publications of Nonne's school, to the effect that a positive reaction in the cerebro-spinal fluid is obtained by the "auswertungs methode" in a considerable percentage of cases of secondary syphilis. Bergl and Klausner[23] obtained the "4 reactions" in florid syphilis. They examined 30 cases, but in what percentage these reactions were obtained I am unable to gather. Fraenkel in 15 cases of recent florid syphilis, without nervous symptoms, obtained a positive reaction in the cerebro-spinal fluid in 5, using 1 c.c. He also finds that the 4 reactions may be present. Perhaps these results are due to inflammation of the meninges to a greater or less extent; under which conditions the complement-binding substance may pass from the blood, where it is abundant, to the cerebro-spinal fluid. It is clear that further experience with the "auswertungs methode," in the cerebro-spinal fluid, is needed in secondary and tertiary syphilis and in dementia paralytica, in order to a better understanding of its value and limitations. Table XXIII. shows the results of the Wassermann test upon a series of cases, increasing amounts of serum and cerebro-spinal fluid being employed. Nos. 1, 6, and 11 were clinically cases of cerebro-spinal lues, all having been under treatment in the infirmary before admission to Cardiff Mental Hospital. In all three the reaction in the cerebro-spinal fluid was negative until 1 c.c. of pure fluid was used. In No. 17 (tabes, not insane) Wassermann was negative even with that amount, positive, however, in No. 17A (general paralysis and tabes; stationary, chronic). No. 5 was clinically undoubtedly a general paralytic in a fairly quiescent condition; it is seen that the reaction was negative once even with 1 c.c. of pure fluid, positive with that amount on another occasion. No. 7, general paralytic, was also positive only with that amount. No. 13 was negative once with 0·2 c.c. of pure fluid. No. 21, general paralysis of the insane, positive with 0·7 c.c. pure fluid. No. 12, a general paralytic, positive first with 0·2 c.c. pure fluid. Nos. 14 (once) and 20, also general paralytics, likewise. In Nos. 16 and 18, clinically uncertain cases, either

cases of general paralysis or cerebral lues, the diagnosis has not been settled by the Wassermann test, and their real nature is still obscure after from two to three years of observation. The non-general paralytics (other cases of mental disorder, without evidence of syphilis) are seen to be uniformly negative in all dilutions. These results show that the histological resemblances which in my first lecture were referred to as existing in respect of some cases of cerebral lues and cases of dementia paralytica have a serological counterpart.

I find that out of 19 cases of dementia paralytica in which 0·2 c.c. of pure cerebro-spinal fluid was used for the test, 11 gave a positive Wassermann and 8 a negative one; and out of 14 cases in which 1 c.c. was used, 10 gave a positive and 4 a negative reaction. Whereas the figures for other forms of insanity were, with 0·2 c.c., all negative in 13 cases; with 1 c.c., 5 positive out of 12; but as 3 of these were certainly (2) or possibly (1) cases of cerebro-spinal lues, only 2 out of 12 were positive in non-general paralytics and non-syphilitics with 1 c.c., as against 10 out of 14 in dementia paralytica.

The deductions I draw from the various experiences detailed above in respect to the employment of increasing strengths of cerebro-spinal fluid amboceptor are that a positive Wassermann with 0·2 c.c. of a 1 in 10 solution indicates dementia paralytica, but a negative reaction with any strength up to even 1 c.c. of the pure fluid does not exclude this disease if only once obtained; that negative reactions with large amounts of fluid are not infrequently obtained in, at any rate, the more quiescent periods of the disease, or in slowly progressive cases; that in such periods and cases the complement-deviation method cannot be relied on for diagnosis between dementia paralytica and cerebro-spinal lues, and this will, as heretofore, need to be made upon clinical grounds.

Frequency of a Positive Wassermann Reaction in Cases of Mental Disorder other than Dementia Paralytica.

In contrast with Table XX., I here give a table (Table XXIV.) embodying the results of the principal workers in respect to cases of mental disorder other than dementia paralytica. Respecting the large percentage of positive results obtained by Fraser and Watson in the serum, these authors give the explanation that no cases over 17 years of age appear in their series; but the percentage of positive results is, they say, stated by Dean to diminish rapidly after the sixteenth year. From the above summary it appears that a large number of observations has been made in respect of the serum in cases of idiocy, imbecility, and mental defect in general, but a comparatively small number in other psychoses. As regards the cerebro-spinal fluid, the number of all kinds examined is small. The positive results with the latter were obtained in psychoses associated with organic changes, a negligible figure being obtained in psychoses usually spoken of as "functional."

Summarising the results of Scölberg and myself with 0·1 c.c. (of 1 in 10) amboceptor as for the authors cited, the following results appear (Table XXV.).

TABLE XXV.—*Percentage-frequency of Positive Reactions in Cases of Mental Disorder other than Dementia Paralytica.*

—	No. of cases.	Serum.	C.S.F.	Form of disorder.
Schölberg and Goodall.	Serum, 17.	6·0		Idiocy and imbecility with epilepsy.
	C.S.F., 3.		0	
	Serum, 29.	3·5		Idiocy and imbecility.
	Serum, 22.	9·0		Insanity with epilepsy.
	C.S.F., 12.		0	
	Serum, 15.	0		
	C.S.F., 7.		0	Dementia præcox.
	Serum, 17.	0		
	C.S.F., 8.		0	Other psychoses.

Subsequent to the above cases we carried out a second series of observations upon cases of insanity other than dementia paralytica, using 0·2 c.c. of a dilution of 1 in 10 amboceptor as a control to our series of cases of dementia paralytica with the same amount. In Table XXVI. are given the two sets of tables—repeating the table relating to general paralytics—for comparison.

I have to observe that there were very few imbeciles amongst the cases of "other psychoses," and these few were all adult persons. For the rest, the most diverse kinds of insanity figure among these cases, including a few epileptic dements. From the figures cited from various authors (excluding those of Fraser and Watson, for the reasons

referred to), and from those of Schölberg and Goodall, it is seen that a positive Wassermann reaction occurs in the serum in idiocy and imbecility, alone or with epilepsy, in a fair proportion of cases, and also in a fair proportion of cases of insanity with epilepsy. But in respect to the "functional" psychoses, the results of two (Muirhead, McCampbell and Rowland) of the three observers cited agree with our first series, and show that a negative reaction occurs. The percentage of 11·29 of positive results with serum in our second (larger series) is no doubt partly due to the inclusion of some instances of adult imbecility and epileptic dementia. With reference to the comparative Table XXVI., it is worth noting that the cases of retarded hæmolysis with the serum are about five times more numerous in dementia paralytica than in other psychoses, which goes to strengthen the evidence for the presence of complement-deviating substance in the former serum. With the cerebro-spinal fluid the cases of retardation are about 13 times as numerous. Our fairly numerous examinations of the cerebro-spinal fluid in non-general paralytics supplement the scanty records available, and show the rarity of a positive Wassermann reaction in this fluid in these cases.

FURTHER EXAMINATION OF THE CEREBRO-SPINAL FLUID IN MENTAL DISORDERS; ESTIMATION OF PROTEINS, NITROGEN (IN PARTICULAR) AND OF CELLS.

I shall now deal with the information we possess with regard to the other two of the "4 reactions" of Nonne in the psychoses—viz., the protein reaction and the cell count. I may remind you that a useful quantitative test for protein for clinical purposes may be carried out by centrifugalising a definite quantity (2 c.c.) of the fluid to be tested and 1 c.c. of Esbach's reagent in graduated Nissl tubes, to hold which in the tubes of the centrifuge special "containers" are necessary. The mixture is centrifugalised for three-quarters of an hour. A deposit amounting to one to two graduations is normal, from two upwards abnormal. But the time appears to have come when we must abandon such rough-and-ready methods of estimation and adopt micro-chemical ones, which the chemist is now furnishing, and of such a rapid and comparatively simple kind that they can be used for clinical purposes. As to this I shall have more to say later. Undoubtedly the great majority of workers now employ a qualitative test, and principally the test with saturated ammonium sulphate, as recommended by Nonne and Apelt (a precipitate, as shown by opalescence, within three minutes—"Phase 1" of the Nonne-Apelt test). My large experience of this method enables me to endorse the statements of others as to its great reliability. In conformity with the course adopted in respect to the Wassermann test I here give the more important results published with the Nonne-Apelt method prior to stating my own experience. (Table XXVII.) If these percentage results be compared with those given by various writers in respect of the Wassermann test in the cerebro-spinal fluid, as recorded in Table XX., it is seen that the Nonne-Apelt protein test is more frequently positive in dementia paralytica than is the Wassermann test. The results obtained in my experience are as follows:—

TABLE XXVII.—*Results of the Nonne-Apelt Test in Dementia Paralytica.*

Author.	No. of cases.	Percentage-frequency of positive reaction.	Remarks.
		Per cent.	
Richter.	117	99·2	1910 (only 11 were weak reactions, of which 8 were stationary cases; 3 cases of tabo-paralysis.)
Wada and Matsumoto.	51	100·0	1909, including early cases.
Hönkl.	85	100·0	1909 or before.
Jachs.	40	82·5	1908 ,,
Kronfeld.	200 (of organic brain disease and "functional psychoses")	99·1 (in dem. par.)	1912.
Bundschuh.	54	100·0	1913.
Rosanoff and Wiseman.	75	90·7	1910. "Butyric" reaction.
Eichelberg.	1020 (G.P.I. and non-G.P.I.)	97·0 (in dem. par.)	1912.
Wolff.	30	100·0	1910.
Bisgaard.	110	98·0	1913.

TABLE XXVIII.—*Nonne-Apelt Test ("Phase 1" "Positive"). (Schölberg and Goodall.)*

Dementia Paralytica.

Number of times done, 147.

Positive	125	85·03 per cent.
Negative	22	14·96 ,,
	147	99·99 ,,

It will be seen that the figure from which our percentages are drawn compares favourably with the figures of most of the writers cited, theirs being lower; but with this test, as with the Wassermann, our percentage of positive results is lower than that of the writers cited. For this fact I invoke the explanation that our patients were in several instances in a quiescent phase of the disease when examined. Our experience bears out the conclusion arrived at by a comparison of the Nonne-Apelt and Wassermann tables of other observers, and shows that the former test is the more frequently positive in cases of undoubted dementia paralytica; for with the Nonne-Apelt we obtained 85 per cent. of positive results, with the Wassermann test, even when 0·6 c.c. of amboceptor 1 in 10 was employed, our positive results in the cerebro-spinal fluid of the same patients amounted to only 68·42 per cent., and with the serum only to 72 per cent. It has to be pointed out, however, that the Nonne-Apelt test percentages are based upon very many more instances than are those of the Wassermann reaction, and our recent experiences with the pure cerebro-spinal fluid, which I have detailed in Table XXVIII., show that some positive Wassermann results are missed if even 0·6 c.c. of 1 in 10 of the cerebro-spinal fluid is the highest amount taken. The very numerous "repeat-observations" of Schölberg and myself, in the same patient, show that the Nonne-Apelt is more frequently positive in a given, slowly progressive case than the Wassermann test. To illustrate this point I adduce the following typical instances from the tables in my possession:—

(W. T. M.) Wass. 0 three times; N. A. + same 3 occasions.
(E. J.) ,, ,, ,, ,,
(F. H.) ,, ,, ,, ,,
(W. G. F.) ,, ,, ,, ,,
(S. J. C. K.) Wass. 0·4 times, hæmolysis ret. twice; N. A. + 6 times.

And in all the cases strengths of cerebro-spinal fluid much exceeding the ordinary strength were employed for the Wassermann test.

As regards the Nonne-Apelt test during a remission of general paralysis, I find that of 15 occasions upon which the test was made in this state it was positive in 12, negative in 3. As far as these figures go, the protein test is much more reliable as indicating the continued existence of the disease than the Wassermann, for with the latter a positive result was obtained as often as a negative during a remission. Continuing the inquiry as to the validity of the Nonne-Apelt test, I have collected the results of various observers in respect of the frequency of occurrence of a positive reaction in "functional" psychoses, and psychoses associated with organic disease of the nervous system (and other than dementia paralytica). (Table XXIX.)

TABLE XXIX.—*Percentage-frequency of Positive Results with the Nonne-Apelt Test in Mental Disorders other than Dementia Paralytica.*

Author.	No. of cases.	Positive results.	Remarks.
		Per cent.	
Richter.	133	10·0	1910. Gave a weak reaction, and were mostly cases of organic changes; thus, cases of senile dementia or of alcoholism.
Eichelberg.	1020 (G.P. and non-G.P.I.)	80·0 (Non-G.P.I.)	Cases of lues cerebri.
Wada and Matsumoto.	15	6·6	1909. The one positive result weak, and later negative (an epileptic).
,,	6	33·0	Dementia præcox.
,,	11	100·0	Cases of lues cer.-spinalis.
Jachs.		37 5	1908. Cases of lues cer.-spinalis.
,,	30	13·3	Epileptics.
,,	18	16·6	Idiots.
,,	13	23·0	Chronic alcoholics.
,,	20	10·0	"Ordinary psychoses."
Kronfeld.	200 (organic brain disease and "functional" psychoses)	12·1 (Non-G.P.I.)	1912. ("Functional" psychoses.)
Karpus.	22	4 8	1912. Epileptic insanity.
Rosanoff and Wiseman.	333	10·8	1910. (Various psychoses. "Butyric" reaction.)
Redlich, Pötzl, and Hess.	17	0·0	1910. Epileptic.

A reference to the table shows that a positive reaction is obtained in quite an appreciable number of these conditions, even when cases of lues cerebri are excluded; whereas in similar psychoses the results recorded with the Wassermann reaction have been negative, if one excepts those of Karpus and Kronfeld (see Table XXIV.); but even theirs are on the whole less frequently positive than the Nonne-Apelt results. With reference to this point the results of Schölberg and myself are as follows:—

86 cases of various psychoses other than dementia paralytica, and unassociated with cerebro-spinal lues.	Nonne-Apelt test + in 9·30 per cent.
62 cases of various psychoses (the same cases as above).	Wassermann positive in the cerebro-spinal fluid in 1·61 per cent. when 0·2 c.c. of 1 in 10 amboceptor used, in 7 per cent. when up to 0:6 c.c. used (see Table XXII.).

Whilst, therefore, the Nonne-Apelt test is considerably more frequent in non-general paralytics than the Wassermann test when the latter is performed with the usual strength of amboceptor, there is but little difference between them when, as is frequently necessary for diagnostic purposes, the higher strength of amboceptor is employed.

To summarise in respect to the value of the Nonne-Apelt test: in undoubted dementia paralytica it is more often positive than the Wassermann test with the cerebro-spinal fluid; it is obtained more consistently throughout the course of the disease; it is more reliable as revealing the persistence of the disease in remissions. On the other hand, it is less reliable in diagnosis, occurring oftener in cases of insanity which are not cases of either dementia paralytica or cerebro-spinal lues.

Recently Dr. Stanford,[24] research chemist at the Cardiff Mental Hospital, has published results of a series of comparative studies upon the cerebro-spinal fluid in cases of dementia paralytica and of other forms of insanity (including insanity with epilepsy and senile and terminal dementia), these studies having hitherto been concerned with the density and the nitrogen-content of the fluid. In respect to density he finds that this is higher in dementia paralytica than in other conditions, with the exception of epilepsy with insanity. In four cases of the former disease in which the density figure was particularly high the patients were very near death; in two in which they were uncommonly low the disease was in remission. The results as a whole go to show that there is in this disease a steady, progressive, and abnormal destruction of cerebro-spinal tissue, a conclusion borne out by the observations which follow. As regards nitrogen-content, the method employed consists in the estimation of nitrogen, in hundredths of a milligramme, contained in 1 c.c. of cerebro-spinal fluid. In dementia paralytica the N number was between 20 and 30 in 15 out of 26 cases; of three cases in which it was below 20 two were in remission and one was in an early phase of the malady; of the remaining eight cases (above 30) seven were advanced, one was at the commencement of the disease. A striking instance is given in which the number was only 16·1 in remission, 23·7 on relapse. In various other kinds of insanity (imbecility, manic-depressive, dementia præcox, paranoia, confusional) the N number was never above 25 and only four times over 20 out of 17 tests made. So that a marked difference exists between the cases of dementia paralytica on the one hand, and other kinds of insanity on the other, if one excepts cases of senile and terminal dementia, in which the N number is also high. Increased density and higher N number commonly go together, but in some cases, especially in epileptics, this is not so, and low or moderate N numbers go with high density figure, which, as Dr. Stanford observes, points to the presence of abnormal quantities of other constituents (non-nitrogenous) in some cases. By the courtesy of Dr. Stanford I am able to avail myself of his N numbers in a series of cases of dementia paralytica, and another series of non-general paralytics. These I have set out in the following tables (Tables XXX. and XXXI.), in parallel columns, with the results of the Wassermann reaction as obtained with three strengths of amboceptor, with those of the protein test, and with the cell counts.

The chief impression gained from a survey of Table XXX. is that a failure to record the presence of the disease is—although not frequent—more frequent in the case of the Wassermann and the cell tests than in that of the protein and nitrogen tests. Thus, in the blood Wassermann is negative or (once) incomplete in 10 out of 30 instances in which 0·6 c.c. serum was employed, and likewise with respect to the cerebro-spinal fluid. The cell test was practically negative in 7 out of 31 instances. Whereas the protein test was negative only 3 times out of 34, and the nitrogen test 3 times out of 35 (taking 20 as the lowest correct N number). This comparison therefore bears out what has already been said as to the greater certainty of the protein test in known cases of dementia paralytica, and further demonstrates the accuracy of the nitrogen test as furnishing evidence of katabolism. From the experience gained in the comparative tests, I think it very probable that it will be found that a considerable nitrogen number exists when the protein test is merely faintly positive. It would be of much interest to perform these tests in those unusually complete remissions which are sometimes met with, and I believe more frequently in the private class of patient, from the points of view of their absolute and comparative utility. One would hope to find in the nitrogen test, with further experience, one means (and probably

the most accurate) of ascertaining the existence, or the approach, or termination, of anabolic and katabolic processes.

Turning next to Table XXXI., in which the various tests are compared in the respect of cases of insanity, non-general paralytics, the general impression gained is that of a high degree of accuracy in respect of all the tests. The Nonne-Apelt results are correct in 100 per cent. of the cases; it is interesting to note that the only positive reactions occurred in the two instances of syphilis (but see the last case, senile mania, recorded after the above remarks were written). The nitrogen test is remarkably correct throughout, assuming that the upper limit in cases unknown to be associated with katabolic processes is 20, the only incongruous result being with the third instance, of delusional insanity. Its result in the two instances of cerebro-spinal lues is suggestive, the figure being very high in B., who died (December, 1913) after the test was made, and who was degenerating rapidly at the time, and low in that of E. K., who was in a much better condition physically, and who left (5/1/14) after the test was performed. The cell count was correct in practically 100 per cent. of cases, the number of cells in the first case (B) of lues being possibly lower than might have been expected.

Cell Content of the Cerebro-spinal Fluid in Dementia Paralytica and in other Forms of Mental Disorder.

In conformity with the method adopted in respect to the other tests I give here the results obtained by the principal observers (Tables XXXII. and XXXIII.).

TABLE XXXII.—*Increase of Cells in Cerebro-spinal Fluid in Dementia Paralytica.*

Author.	No. of cases.	Cell increase.	Remarks.
Henkl.	85	Increased in 100%	1909
Schoenbrunn.	—	,,	,,
Wada & Matsumoto.	51	Increased in 98%	,,
Wada & Matsumoto (from literature).	390	,, 91%	,,
Jachs.	40	15 to 161 per c.mm.	1908
Kronfeld.	200	Increased in 95% (G.P).	1912. "Organic brain disease or functional psychoses."
Rosanoff & Wiseman.	75	Increased in 88%	1910
Wolff.	30	,, 93%	,,
Bisgaard.	93	,, 90%	1913

From a *résumé* of the above table and the one following it appears that the cells in the cerebro-spinal fluid are increased in a rather smaller percentage of cases of dementia paralytica than obtains for the positive protein test, though the amount of the increase in particular cases is not stated. As regards psychoses other than dementia paralytica, leaving on one side cases of cerebro-spinal lues, it is seen that in epileptic insanity there is an increase of cells; the figures in respect to dementia præcox are too small to receive attention. The figures of Kronfeld, and of Rosanoff and Wiseman, are

TABLE XXXIII.—*Increase of Cells in Cerebro-spinal Fluid in Non-general Paralytics (other Psychoses or Organic Disease of the Cerebro-spinal Axis with Psychosis).*

Author.	No. of cases.	Cell increase.	Remarks.
Wada and Matsumoto.	64	Increased in 84%	1909. Cerebro-spinal lues.
,, ,,	97	,, 4%	1909. "Normal cases."
,, ,,	6	,, 33%	,, Dementia præcox.
,, ,,	15	,, 6·6%	,, Various psychoses. At second examination increase disappeared (one case an epileptic).
Voisin.	34	Increased in less than 14·0%	1910 Epileptics ("some" had increase after status).
Jachs.	8	17 to 62 per c.mm.	1908. Cerebro-spinal lues.
Kronfeld.	200	Increased in 1·9% (non-G.P.).	1912. "Organic brain disease and functional psychoses."
Karpus.	22	Increased in 18%	1912. Epileptic insanity.
Rosanoff and Wiseman.	333	,, 0·3%	1910. Various psychoses.

particularly instructive, since in all their cases a protein test was done contemporaneously. These show that whereas in psychoses other than dementia paralytica the protein test is positive in 12 per cent. and 10·8 per cent. of cases, the cells are increased in only 1·9 per cent. and 0·3 per cent. of the same, a result which points to the superior value of the cell count in diagnosis. Turning now to the observations of Schölberg and myself my examination gives the following result in respect to dementia paralytica. (Table XXXIV.)

TABLE XXXIV.

No. of Cells in Cerebro-spinal Fluid per c.mm.
Dementia Paralytica.

No. of times counted, 96.		Per cent.
Over 5 cells (Mostly very abundant).	79	82·29
Five or less	11	11·45
None	6	6·25
	96	99·99

These results accord well with those of the Nonne-Apelt test (which was positive in 85 per cent. in dementia paralytica); and as with that so with this test, a positive result is obtained more frequently than with the Wassermann test, although fewer cases were done with the last mentioned. The numerous "repeat" observations which were made justify the statement that, unlike the protein test, the cell count test is not more frequently positive in a given, slowly progressive case than the Wassermann test. As regards remissions: in 13 of 15 cases examined in remission the cell count was found to be abnormally high—that is, it did not diminish in association with the remission.

Our results in respect to the increase or otherwise of the cell count in psychoses other than dementia paralytica were as follows. These cases illustrated various psychoses, being the same cases as formed the material for the protein test; cases of cerebro-spinal lues are, as in that instance, excluded. (Table XXXV.)

TABLE XXXV.

Other Mental Disorders.

No. of times counted, 73.		Per cent.
Over 5 cells (Less abundant than in D.P.).	13	17·80
Five or less	16	21·93
None	44	60·27
	73	100·00

These figures are much above those of Kronfeld and of Rosanoff and Wiseman (1·9 per cent. and 0·3 per cent.), to which I have referred, and are practically the same as the figures of Karpas for epileptic insanity (18 per cent.), but our cases were mixed ones, and epileptic insanity furnished only a fair proportion, purely functional psychoses and secondary dementia furnishing proportional contingents.

Summarising my experience of the cell percentage test, a positive result is more often obtained in undoubted dementia paralytica than with the Wassermann test, and in a percentage only slightly less than that furnished by the protein test; it is not obtained more consistently throughout the disease than the Wassermann; it is more reliable than the latter in revealing the presence of the disease during a remission; it is considerably less reliable in diagnosis than either the Wassermann or the protein test, occurring in a much larger percentage of cases of insanity which are not cases of either dementia paralytica or cerebro-spinal lues.

Comparison of Results of the Tests.

The time at my disposal will not allow me to bring before you illustrations of the relationship between the protein and cell percentage tests on the one hand and clinical stages and phases of dementia paralytica on the other, as was done in the case of the Wassermann test; such illustrations are to be found in the tables incorporated by Schölberg and myself in our paper read before the recent International Congress of Medicine; therefore I must content myself with the statement, which I base upon personal experience, that the lack of correlation between the result of the test and the clinical condition which has been demonstrated in the last-mentioned case exists also in respect of the protein and cell percentage methods. At the most it can be said that, just as the Wassermann test tends to be feeble or negative in slowly progressing or stationary forms of the disease, so the other two tests tend to be feeble or negative in similar conditions. As to a parallelism between the results of the three tests (Nonne-Apelt, cell percentage, and Wassermann in the cerebro-spinal fluid), I find that all who deal with this point amongst the authorities I have cited are agreed that there is none such. Analysing the results of Schölberg and myself, I find that the three tests were made contemporaneously in each of 62 cases, in each instance 0·6 c.c. of the (1:10) patient's amboceptor being used for the Wassermann test. In 67·7 per cent. all three tests were positive. This indicates a considerable degree of parallelism, but, although the amount of amboceptor used was high, it is very probable from what has gone before that a higher percentage of positive Wassermann reactions would have resulted had pure cerebro-spinal fluid been used and an even closer agreement would have resulted. This result is not in keeping with the statements of other workers; nevertheless, it is based upon recorded tables of comparison, confirmed and amplified by further work since, whereas the other statements are not so supported. The accompanying table (Table XXXVI.) has, perhaps, the merit of novelty, and, at any rate, illustrates in an interesting manner the progressive weakening or diminution of the complement-deviating substance in the serum in different stages of syphilis. I have to thank Dr. Schölberg

Polynucleosis in the Cerebro-spinal Fluid in Dementia Paralytica.

By the expression "increased cell count in the cerebro-spinal fluid" is meant for all practical purposes a lymphocytosis.

Pappenheim[25] has published observations which have an interesting bearing upon this matter. He argues that the hyperleucocytosis met with in the blood in dementia paralytica in connexion with seizures, and that found, according to him, in the cerebro-spinal fluid in the same, and in connexion with the febrile attacks of unknown origin which occur in this disease, are due to a common cause. The characteristic of the cell increase in the cerebro-spinal fluid at such times is, according to Pappenheim, a polynucleosis, as it is in the blood. The cause of this exacerbational polynucleosis he believes to be an increased production of toxin. He cites Villaret and Tixier (Comptes Rendus, 28/7/06) as having noted a similar polynucleosis in the cerebro-spinal fluid in two cases of tabes with exacerbation of symptoms. Bergl and Klausner[26] find frequently in florid syphilis a high percentage of polynuclear leucocytes in the cerebro-spinal fluid; in later, chronic conditions lymphocytes and plasma cells appear, polynucleosis returning with exacerbations. The only writers besides Pappenheim who appear to have noted a polynuclear increase in the cerebro-spinal fluid of general paralytics are Roubinovitch and Paillard[27] (at the time of a seizure), and Como and Xanthopoulos.[28] On the other hand, there are competent observers, such as O. Fischer[30] and Kafka (two others are mentioned by Kafka[29]), who either deny that there is a polynucleosis in this fluid in dementia paralytica in association with exacerbation or deny any connexion between these conditions, since they find polynucleosis without clinical change and exacerbations without polynucleosis. Any polynuclear increase in the liquor these writers ascribe simply to an increased local meningitis, and not at all to a sudden increase in toxin production. Furthermore, any transitional and accidental polynucleosis in the liquor is not associated with polynucleosis in the blood, such as I drew attention to in my third lecture. At my request my colleague, Dr. D. J. Jackson, examined between 80 and 90 samples of the cerebro-spinal fluid of general paralytics, in the Fuchs-Rosenthal counting chamber and in centrifugalised deposits, these samples being removed in remissions and during and after seizures and pyrexial attacks. His observations lend no support to Pappenheim's statements, for whether in remission or in exacerbation states the dominant cell was the small lymphocyte, accompanied by some large lymphocytes, and polynuclears were conspicuous by their absence.

Observations on Complement in Cerebro-spinal Fluid.

By a natural process of association one passes from the consideration of meningitis of a localised kind in dementia paralytica, to a matter of theoretical interest—namely, the question of the existence or absence of complement in the cerebro-spinal fluid in this disease. The presence of complement in this fluid has been ascribed to the existence of meningitis in greater or less degree. Margulies[31] states that cerebro-spinal fluid has normally no hæmolytic property, but that in acute meningitis it acquires such, and in marked degree, against sheep's blood corpuscles; it contains, in fact, immune body and complement, like the blood serum. The latter statement is perhaps based upon the work of Weil and Kafka. The change is ascribed to transfusion of serum, as a result of the greater permeability of the meningeal vessels. Ciuca[32] examining the cerebro-spinal fluid in 30 normal persons found alexine absent in all. It was also absent in pathological conditions without meningeal complications; thus, in infectious fevers, diseases of the kidney and lung, hemiplegia, gumma of the brain, and dementia paralytica (three cases). In tuberculous meningitis, however, it was also absent. In certain diseases in which the serum contained specific antibodies these also were absent from the cerebro-spinal fluid. Hauptmann[33] and Weil and Kafka[34] state that complement is absent from this fluid in dementia paralytica; the last mentioned further find it to be absent even when in rich amount in the blood, as it is in exceptional cases. But more recently Kafka[35] has modified this statement, finding complement to be present in traces in from 11 to 12 per cent. of cases of this disease, and in these there is usually marked meningeal infiltration, accompanied by high cell counts and albumin. The above statements appear difficult to reconcile with another assertion of Weil and Kafka,[36] that by their technique the permeability of the meninges was found to be about ten times greater than the normal in 97 per cent. of 24 general paralytics. In 23 non-general paralytics there was no increased permeability. But there would not appear to be sufficient evidence that the immune body and complement found in the cerebro-spinal fluid in some cases of dementia paralytica are derived from the blood. A statement by Justschenko[37] as to the varying hæmolytic power of the blood serum in the "organic" disorders—dementia paralytica and dementia præcox, on the one hand, and a "functional disorder, manic-depressive insanity, and normal persons, on the other, led Schölberg and me to test the hæmolytic property of the serum and of the cerebro-spinal fluid respectively, from cases of mental disorder, against sheep's blood corpuscles. We first employed the solutions recommended by the Russian writer—viz., 5 c.c. of a 2 per cent.

solution of serum and 0·2 c.c. of a 10 per cent. suspension of sheep's corpuscles. This mixture was placed in the incubator, shaken at the end of an hour, replaced, and removed at the close of two hours to the ice-chest, and the results read the following morning. According to the author quoted, the serum from the cases of "organic" psychoses mentioned usually gives hæmolysis, that of manic-depressive insanity, and of a normal person, scarcely any. The following results I have to record by this method.

Hæmolysis + or 0.

"Organic" Psychoses.		*"Functional" Psychoses.*	
E. L. Dementia paralytica	0	D. L. Mild mental defect	+ (6 times)
M. B. Dementia with epilepsy	+	B. P. Chronic mania ...	+
D. L. Disseminated sclerosis with dementia	+	C. J. Imbecile	+
C. J. Tabetic general paralysis of the insane	+	M. Delusional insanity	+
F. M. Dementia paralytica	ret.	H. Confusional ,,	0
C. S. ,, ,, ...	+	E. Melancholia	ret.
B. P. Dementia præcox (quiescent)...	0	L. M. Chronic mania ...	+
		C. W. Melancholia... ...	+
		J. M. Dementia (secy.)...	+

ret. = retardation. secy. = secondary.

So that the results are much alike in the two series. In a subsequent and more extensive series of observations, with a view to ascertaining the presence or absence of complement in the cerebro-spinal fluid in dementia paralytica, Schölberg and I proceeded as follows. To 1 c.c. of uninactivated serum 0·5 c.c. of a 5 per cent. suspension of sheep's corpuscles in normal saline was added, and further, undiluted complement from a guinea-pig, in an amount based upon the titre of the same complement, as estimated for the hæmolytic test in the Wassermann reactions, which were done contemporaneously, due allowance being made for the greater dilution of the complement in our special test and for the fact that it was pure. A control tube of the same serum without complement was also put up. Uninactivated cerebro-spinal fluid obtained from the same patient at the same time was used in like manner, but in this case 5 c.c. of the fluid was taken, and a proportionately greater amount of complement was used; the control tube without complement was, of course, prepared in this instance as with the serum. On each occasion a case of dementia paralytica was taken, and one of another kind of insanity (dementia præcox, imbecility, or milder degree of defect, secondary dementia). The general paralytics were in very pronounced phases of the disease. The tubes were treated as described above. Tables showing the results I am unable to reproduce for reasons of space. They show clearly the existence of hæmolytic substances in adequate amount in the "normal" serum (no complement added) in all but two cases of the non-general paralytics, and the like in the general paralytics. In respect to the cerebro-spinal fluid; 14 cases of insanity other than of general paralysis and 14 cases of general paralysis are dealt with. As regards the non-general paralytics there is absence of hæmolysis with the "normal" cerebro-spinal fluid in every case; from which it is to be inferred that complement or hæmolytic amboceptor, or both, are lacking in the cerebro-spinal fluid. The addition of hæmolytic serum (upon the basis of the titre ascertained for the Wassermann test) made no difference except in one case (hæmolysis); the subsequent addition of complement produced hæmolysis in all the other tubes. In 4 out of 14 tubes containing complement H = +, but in the remaining 10 H = slight or absent, showing that either insufficient complement had been used or that amboceptor was deficient, or showing both. The appearance of hæmolysis in 5 out of 8 cases, on adding amboceptor, shows that amboceptor was deficient in them; but in the remaining 3 hæmolysis was brought about on further addition of complement.

As regards the general paralytics (14 cases) there is absence of hæmolysis in all but two of the "normal" tubes, in which it occurred to a slight extent. The addition of hæmolytic serum made no difference except in one case, in which hæmolysis resulted. In the other cases hæmolysis was produced by subsequent addition of complement. In 8 out of the 14 complement-holding tubes H = +; in 4 others H = slight; in 2 others H was absent. In 5 of these last 6 (H slight or absent) hæmoloysis was rendered complete or brought about by adding amboceptor or amboceptor and complement.

The conclusion is that there is absence or deficiency of complement in the cerebro-spinal fluid in dementia paralytica, and there is sometimes deficiency, at any rate, of amboceptor. In these respects the fluid resembles that of the control, non-general paralytics. The above results go to support the statements of Hauptmann, and Weil and Kafka, to the effect that in dementia paralytica complement is absent from the cerebro-spinal fluid, and they go to show that this fluid, in the kinds of mental disease dealt with, resembles the fluid in normal persons in having no hæmolytic properties.

BERI-BERI AT FALMOUTH.—At the last meeting of the Truro and Falmouth port sanitary authority Dr. G. E. Lanyon, the medical officer, stated that during the preceding three months about 700 steamers were "cleared out" of Falmouth, and they had had 14 cases of beri-beri. Dr. Lanyon added that the ships on which these cases occurred had only been on short voyages and the crews had good food, and on one ship a bullock was killed every week.

A CASE OF INTESTINAL OBSTRUCTION,

WITH SOME NOTES ON OPERATIVE TECHNIQUE.

By A. WEBB JONES, M.D. LOND., F.R.C.S. ENG.,
SURGEON AND GYNÆCOLOGIST TO THE EGYPTIAN GOVERNMENT HOSPITAL, ALEXANDRIA.

THE patient, a young Sudanese table servant, was admitted into the Egyptian Government Hospital, Alexandria, suffering from acute intestinal obstruction. On opening the abdomen through the right rectus the obstruction proved to be a coil of the lower ileum which was firmly glued down by lymph and lay in the true pelvis on the left side. On delivery the loop of intestine showed an advanced gangrenous condition. The bowel was therefore clamped, crushed, and divided with the actual cautery a few inches from its junction with the cæcum. The distal end was then invaginated with a purse-string Lembert suture, whilst the coil of gangrenous intestine was severed from its mesentery and drawn on until a portion of healthy bowel came out through the upper end of the abdominal wound. A drain was placed in the pelvis and the abdominal wound partially closed. The gangrenous gut was then severed, and finally a Paul's tube was fixed in the sound bowel immediately proximal to the gangrenous gut. The gut removed was examined by Professor Kartulis. It measured about a foot in length and, situated towards its distal end, presented a typical conical Meckel's diverticulum (also gangrenous).

I am unable to explain definitely the cause of the gangrene, but am inclined to think that the Meckel's diverticulum was accidental and had nothing to do with its causation. With regard to the technique of the operation the method seems to me to have some advantages, as there can be no leakage whatsoever of fæcal matter until after the abdomen is closed—indeed, in this case the flow through the Paul's tube was not established until the patient had regained his bed.

The patient did well, and about a month later the abdomen was opened through the left rectus. The bowel going to the artificial anus was identified by passing a bougie down the external orifice. It was then clamped and divided with cautery about six inches from its orifice. The two ends were invaginated, closed with a purse-string Lembert, and an anastomosis was then made between the proximal end and the transverse colon. Primary union was obtained and the patient made a rapid recovery. He now, however, has a small blind tube of ileum some six inches in length opening on to his abdomen. It secretes a little mucoid discharge, but disturbs him so little that he has refused further operative treatment and left the hospital.

As regards the problem of closing the small living intestinal test-tube, so to say, which remains, it occurred to me that one might have removed the mucous membrane forming the lining somewhat after the manner of an exaggerated Whitehead's pile operation. The inner surface of the gut thus freshened might have been expected to heal into a solid cord. This would have avoided opening the abdomen for a third time.

Although I imagine the case is far from unique I do not remember to have read of one which resembled it in every detail. For this reason, and more particularly because of the problem of how to treat a blind intestinal section, I have thought it worth recording. Perhaps someone of wider experience could say what is the usual fate of a small section of secluded gut opening on the abdominal wall when left to nature. My own case has gone to a remote village in Upper Egypt and is not likely to be heard of again. Similar conditions the result of animal experiments, I am told, are apt to close spontaneously.

Alexandria.

Medical Societies.

HUNTERIAN SOCIETY.—A clinical and pathological evening was held at the Barbers' Hall on Dec. 9th.—Dr. R. Fortescue Fox showed: 1. A case of Myxœdema in a man who had been under the care of Dr. Hertoghe, of Antwerp. The case illustrated rapid improvement under thyroid treatment. 2. A case of Fractured Ulna successfully united by means of a screw.—Dr. Theodore Thompson showed photographs of a man who had Fibro-sarcomata of the Back and Abdominal Wall, which had disappeared under X rays.—Mr. W. Girling Ball showed: 1. A Large Rhabdomyosarcoma removed from the abdomen of a child 3 months old. 2. A Humerus of a woman showing spontaneous fracture due to the presence of a thyroid metastasis about its centre. Microscopically the structure was that of fœtal thyroid. 3. A Gangrenous Foot removed from a soldier. 4. A Gangrenous Hand, also removed from a soldier. The gangrene was due to the severing of a large artery by a bullet. 5. A portion of a Spinal Column showing laminæ that had been shattered by a bullet.—Mr. R. L. Mackenzie Wallis showed X rays of Bullet Wounds and also Two Sovereigns that Mr. D'Arcy Power had extracted from the back of a soldier. These had been driven out of his belt into the flesh by a piece of shrapnel. So great had been the force that the lettering of one sovereign had stamped itself on the other.—Dr. A. C. Jordan showed a simple but accurate method of X ray localisation of bullets and other foreign bodies on the principle of parallax.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on Nov. 20th, Dr. J. H. Willett (Liverpool), the President, being in the chair.—Professor J. B. Hellier (Leeds) exhibited a specimen of Cystic Sarcoma of the Uterus removed from a multipara aged 46. Menstruation had been irregular and infrequent for two years, and the patient had noticed a steadily growing lump in her abdomen for 14 months, until it reached the size of a four months pregnancy. The tumour was removed by supravaginal hysterectomy, and was then found to be converted into a multilocular cyst filled with yellowish serous fluid.—Dr. J. E. Gemmell (Liverpool) exhibited a specimen of Fibroids Complicating Pregnancy from a primipara aged 41. In this case it was considered safer for the patient to have the pregnant uterus removed than wait for Cæsarean section.—Dr. A. Stookes (Liverpool) exhibited a specimen of Fibroids Complicating Pregnancy from a primipara aged 30, five months pregnant. The fibroid had undergone cystic degeneration.—Mr. W. R. Favell (Sheffield) related a case of Labour Obstructed by Fibroid from a 3-para aged 37 years. The patient had been in labour for a week, during which time meconium was passed and fœtal movements ceased. The child was dead and presented by the breech. Panhysterectomy was performed.—Mr. Favell also read the notes of a case of Chorion Epithelioma from a patient aged 23, whose only pregnancy ended in a two months abortion in September, 1913. The uterus was removed a year later with mass behind it with a history like ectopic gestation. Later a small bleeding growth in the vagina was removed. The patient was now gaining weight.—Mr. Miles H. Phillips (Sheffield) described a case of Hydrometra, the size of a seven months pregnancy, removed from a multipara aged 56 years, who had been married 30 years. The uterus consisted of a thin-walled cyst lined with columnar cells. The cervix was blocked with fibrous tissue.—Mr. W. W. King (Sheffield) read notes of (1) a case of Concealed Accidental Hæmorrhage, with Hæmatoma in the Broad Ligament, treated by Cæsarean Hysterectomy; and (2) a case of Acute Hydramnios in a 9-para, aged 30, six months pregnant. The symptoms were rapid enlargement of the uterus, with great tenderness and abdominal pain. Delivery was followed by severe post partum hæmorrhage.

Reviews and Notices of Books.

The Life, Letters, and Labours of Francis Galton.

By KARL PEARSON. Vol. I. Birth, 1822, to Marriage, 1853. Cambridge: at the University Press. 1914. Pp. 246. Price 21*s.* net.

THIS book is not a "life" in the sense of Trevelyan's "Life of Macaulay," Lockhart's "Life of Scott," or Boswell's "Life of Johnson," and "the indolent reader" to whom Professor Pearson refers in his preface will certainly fight shy of it. But as a memorial to a loved and honoured teacher by a brilliant pupil it is in literal truth a masterpiece, containing an amount of solid work which is far from being adequately represented by the mere number of pages. As Professor Pearson implies in his preface, the work deals to a great extent with Charles Darwin as well as with Francis Galton; both were grandsons of Erasmus Darwin, both brought to the study of biology and all that it implies unwearied patience and unflagging industry. But in Galton's view heredity and ancestry played a more important part than they did in that of Darwin, at all events until 1869, when he was converted by reading Galton's "Hereditary Genius" to a belief that intellectual ability is hereditary. Darwin's letter to Galton and the latter's answer, both of extreme interest, are reproduced at p. 6 of the book.

Ancestry, therefore, being so important a constituent in a man's mental and physical qualities, Professor Pearson, as a whole-hearted follower of Galton, has set himself to show how his master was moulded by his ancestry—and what an ancestry it is! The pedigree plates contained in a pocket at the end of the book show that Galton, even in his immediate descent and its collaterals, drew strains from Darwins, Barclays, Sedleys, and Camerons, while the astounding Darwin pedigree (that marked E) goes back to the early Frankish kings, and contains the names of most European Royal families down to our own Elizabeth's time. In physique as a whole, says Professor Pearson, "Galton was in popular language, 'not a Darwin.' It is to the mental characters that we must turn for likeness." And he continues, "Francis Galton was physically and mentally a blend of many ancestral traits. Whether they were 'unit characters' or not concerns us but little here. What we do realise is that they were not the product of environment, whether of home, or school, or college. Few men have had more noteworthy ancestry in many lines than Francis Galton; that such ancestry should produce, not several, but one brother alone of this marked social value can puzzle only those who have not considered the wide range of possible variations which arise as we rotate the kaleidoscope of heredity. If on the average only one in four brothers of distinguished stock reaches first-class eminence, can we not only understand quite well how Charles Darwin and Francis Galton stand alone, but also appreciate how greatly the chances of perpetuating ability are reduced when men of able stocks leave in modern conditions but one or two children to preserve their name?" Herein, adds Professor Pearson, lies the key to Galton's demand that "eugenics" should pass as rapidly as possible from the laboratory to the market place.

After the end of Chapter II. comes that portion of the book with which Professor Pearson's "indolent reader" will probably commence—namely, the account of the childhood and boyhood of Francis Galton. It is interesting to note that even at the age of 8 years his schoolmistress reported most highly of him, but added, "the young gentleman is always found studying the abstruse sciences." We only wish that we had space to follow Francis Galton through his life so far as this first volume covers it, for as told in his letters and the illuminating comments of Professor Pearson it it of extraordinary interest, while the reproductions of portraits and sketches are most valuable. Many of the portraits are silhouettes, a kind of portrait which with all its deficiencies yet gives an admirable idea of its subjects. How characteristic is the silhouette portrait of Erasmus Darwin and his father, Dr. Erasmus Darwin, playing chess, which is reproduced at p. 14, or that of Erasmus Galton, Francis's elder brother, in his middy's uniform, at p. 69! So with regret we leave this enthralling work, a regret tempered by the knowledge that another volume of it is in store.

Diseases of the Rectum and Anus.

By P. LOCKHART MUMMERY, F.R.C.S. Eng. With 102 illustrations. London: Baillière, Tindall, and Cox. 1914. Pp. viii.–348. Price 7*s.* 6*d.* net.

THIS is a sound book and a practical one. These are its outstanding features. The author does not present any new or subversive hypotheses, with the possible exception of a suggestion thrown out that the propagation of carcinoma is due to our habit of burying our dead: he is presumably an advocate of cenotaphia. To say that the work is practical is meant for high praise. For the successful treatment of rectal disease a level head is more useful than an exuberant imagination. It is essentially a practical subject, and does not give much opening for theoretical disquisitions on German professorial lines.

It is pleasing to find a special chapter on antiseptic technique in relation to operations on the rectum, in which particular stress is laid on the necessity for taking as much care about asepsis in rectal operations as in those on other regions. To behave as if the rectum were necessarily a septic region, and ordinary precautions were therefore not called for, is wrong-headed; but we must confess that we have seen surgeons operating in general hospitals apparently under the influence of this idea. We agree with the author's criticisms here.

Mr. Mummery very rightly regards adequate drainage as one of the first essentials for success in rectal surgery. It is equally important in dealing with a fistula, a fissure, or piles by the operation of ligature, which he regards as the method of election. He describes, however, an operation for piles which he has designed and which is a slight modification of Laplace's operation, the only difference being that Laplace begins to cut away the pile at its upper extremity, Mr. Mummery at its lower. Now in both cases the cut edges of the mucous membrane are united by suture; and in both the rule of ensuring adequate drainage is overlooked, with the consequent risk of submucous infection. Neither of these operations is to be recommended. Mr. Mummery's operation for the treatment of prolapse has the merit of ingenuity and simplicity, but it would appear to hold out hopes of success only in cases where the prolapse is mainly one of the posterior rectal wall.

He mentions at length a condition which he calls "hæmorrhagic proctitis," but the evidence that this is a clinical entity and not a localised symptom of general disease is slight. There is a lucid account of the technique of the abdomino-perineal operation for excision of the rectum for carcinoma, but we looked in vain for any pronouncement on the question which vexes proctologists to-day—e.g., what class of case is suitable for this operation? Should it be attempted, for instance, in a fat but otherwise healthy man aged, say, 65? We should have liked to learn the author's answer to this particular question. The book ends with a short and vigorous chapter on foreign bodies in the rectum.

MISCELLANEOUS VOLUMES.

AT this season of the year a number of year-books, diaries, and so forth demand notice. Among the diaries issued by the firms of Messrs. John Walker and Messrs. Cassell and Co. will be found some suitable to various tastes and requirements. Both firms issue an insurance coupon with their diaries for £1000, which becomes valid on payment of a small registration fee. Both firms have some useful wall calendars and date-blocks.

A feature of Messrs. Walker's diaries is the easy interchangeability of the contents, either by an ingenious arrangement by which the whole contents of the diary slide into a metal grooved slip fixed centrally between the inside of the covers or by means of the well-known loose-leaved system, the leaves being held in place by a split-ring. In the case of the more expensive bindings—and these diaries can be had bound in velvet calf, real seal, morocco, and crocodile, making ideal and dainty presents—this is a distinct advantage, as the covers can be used over and over again, refills being supplied at very cheap rates, while the loose-leaved system makes it possible to insert or detach easily any leaf or leaves that may be required. In size the diaries are variously suitable for the vest, hip or breast pocket, and the rulings are for a week at an opening, one day, two days, or a week to a page, while the prices vary from 6*d.* to 8*s.*

Letts's Diaries (Messrs. Cassell and Co.) are issued with rulings similar to the foregoing and in sizes to suit all requirements and bindings to suit every taste, the prices ranging from 1*s.* upwards. In addition to the usual form of pocket diary this firm publishes a wide selection of scribbling diaries interleaved or not as required, with blotting paper. Convenient diary cases with pockets for stamps and various purposes, the diary which they are intended to contain being renewable as required, are obtainable. *Letts's Medical Diary*, *1915*, is a useful one, and contains much information of service to medical men. The diary shows a week to an opening, with space for recording the number of the ledger folio, patients' names, and visits made, while pages are provided for keeping a cash account, for professional engagements, and for the names and addresses of patients. According to the binding the prices vary from 2*s.* 6*d.* to 4*s.*, and from 4*s.* to 5*s.* 6*d.* respectively for the two sizes, which are ruled for either 54 or 108 patients.

The Doctor's Daily Register, comprising a combined visiting list and account book designed by Fred. W. Menzies, A.S.A.A., C.P.A. (U.S.A.) (Edinburgh and London: George Waterston and Sons, Limited), enables the medical man or his bookkeeper to record results in a simple and accurate manner. The system is self-checking. Records of visits having been made by the practitioner, the accounts may afterwards be written up, filed, and kept quite independently of him. The sheets of which this register is composed are fastened in a leather case 8 by 5½ inches by means of two small binding screws, and are ruled to deal with a month at each opening and to meet all possible requirements, including panel patient entries. A useful feature of the system is that not more than a month's supply of sheets need be carried at a time. A complete outfit with sheets for 12 months costs 10*s.* 6*d.*, and refills can be obtained for 3*s.* 4*d.* per 100 sheets. The system is a most convenient one.——*The Professional Pocket Book*, or daily and hourly engagement diary for 1915, according to the plan of the late Sir Julius Benedict (London: Rudall, Cart, and Co. Price 1*s.*), is intended principally for musical engagements, but the book presents features which may suit the requirements of other professions. The system provides for the entry of the hour as well as the day of an engagement. The diary consists of three small notebooks, each of which is ruled for four months, and one only of the books need be inserted between the covers of the diary at a time, thus saving bulk.——*The Live Stock Journal Almanac, 1915* (London: Vinton and Co., Limited. Price 1*s.*), contains many articles of interest to farmers and breeders of horses and cattle. The diary portion, which shows two pages to a month, includes a breeder's table.

Year-book of Scientific and Learned Societies of Great Britain and Ireland (London: Charles Griffin and Co. Pp. 376. Price 7*s.* 6*d.* net) is a record of the work done in science, literature, and art during the session 1913–1914, by numerous societies and Government institutions. It is compiled from official sources, and contains in classified order according to subjects lists of the societies, with their addresses, names of officers, dates of meetings, number of members, fees, publications, and so forth, together with the papers read before the societies during the session. The section devoted to medicine occupies pages 315 to 366; biology, which includes microscopy and anthropology, pages 143 to 188; and psychology, pages 278 to 282. Lists of papers on medicine and allied subjects will be found also under the headings of the Royal Society, the Royal Institution of Great Britain, and the British Association for the Advancement of Science, which come under the main heading of "Science Generally." A good index adds to the convenience of this useful publication, which is now in its thirty-first year.

Paton's List of Public Schools and Tutors, 1914 (London: J. and J. Paton, 143, Cannon-street, E.C. Pp. 1160. Price 2*s.*), which is compiled with a view to assisting parents in their choice of schools, is now in its seventeenth year. It contains a large amount of information concerning many of the best English schools for boys and girls. A list of scholarships and exhibitions, details regarding preparation for the Services, professions, and agricultural training for women, add to its value, as does also a map of the greater part of the British Isles, with the towns clearly indicated where public schools are situated. It may be pointed out that since the book was printed many school authorities have notified their willingness to reduce their fees for the children of officers or of those whose incomes have been considerably diminished owing to the war.

Low's Handbook to the Charities of London, 1914 (London: Sampson Low, Marston, and Co., Limited. Pp. 252. Price 1*s.* net), is too well known to need any commendation from us. The present issue (the seventy-ninth) gives the objects, date of formation, offices, income, expenditure, invested funds, bankers, treasurers, and secretaries of over 1200 charitable institutions, which are arranged in alphabetical order. The preface has for its theme this year the Shaftesbury Society and Ragged School Union, and a portrait of Sir John Kirk, J.P., the director of the society, forms the frontispiece.

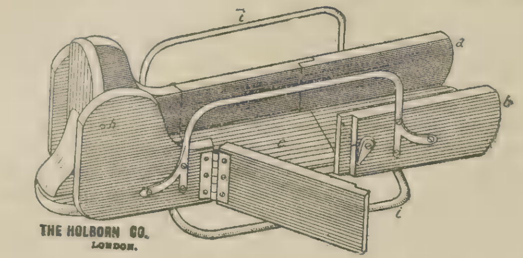
From Messrs. Adam and Charles Black we have received three reference books, *Who's Who, 1915* (Pp. 2376. Price 15*s.* net), the *Englishwoman's Year Book, 1915* (Pp. 448. Price 2*s.* 6*d.* net), and the *Writers' and Artists' Year Book, 1915* (Pp. 172. Price 1*s.* net). All are now too well known to need detailed description. In *Who's Who* the number of biographical notices of persons of distinction by social consideration, official position, or achievement in various walks of life is constantly enlarging, and the book has become an indispensable work of reference. The *Englishwoman's Year Book*, edited by G. E. MITTON, covers the field relating to women in regard to education, professions, social life, sport, and philanthropic effort. The table of "Records for Women" shows by concrete examples the appearance of women in the front rank of their selected fields of work, a result which is equally shown in the table of (women) experts. An exceedingly interesting and useful feature for students and women workers is the directory of boarding houses for women. It seems difficult to think of any field of activity for women concerning which much useful information cannot be obtained from this volume.——The title *Careers: A Guide to the Professions and Occupations of Educated Women and Girls* (London: The Women's Employment Publishing Company, Limited, 5, Princes-street, Cavendish-square, London, W. Fourth edition. Pp. 336. Price 1*s.* 6*d.*) sufficiently indicates the nature of a useful book which is issued in connexion with the Students' Careers Association and the Central Bureau for the Employment of Women. The articles on the profession of medicine are written by women doctors; the Viscountess Bryce furnishes an introduction to the book, and a foreword is supplied by Miss Mary G. Spencer.

New Inventions.

INTERRUPTED BOX AND LONG SPLINTS FOR COMPOUND FRACTURES OF THE LEG AND THIGH.

I WISH to draw attention to the following type of splint which I have devised and have employed with satisfaction for the past six years. I have not seen it described, and therefore put it before the profession in the hope that it may prove useful to others. The splint (Figs. 1 and 2) consists of a back splint with a foot-piece and two side splints. It is designed in such a way that when the catches are released and the hinged parts turned back the portion of the limb which requires dressing can be attended to with the minimum amount of movement to the broken ends of the bones, and consequently practically without any pain. *a* and *b* are the two side splints with hinge and catch shown. In the lower end of each of these a hole (*h*) is bored. Through these holes passes a transverse iron bar (*c*) which projects from the upper part of the foot-piece of the back splint. When the splints are fixed in position this bar helps to keep them steady. The interrupted portion of these splints between the hinge and the catch is bridged over by strong iron brackets (*i*). The back splint (*c*) is also interrupted and flanked with iron brackets and provided with hinge and catch similar to the side splints as shown in the diagram.

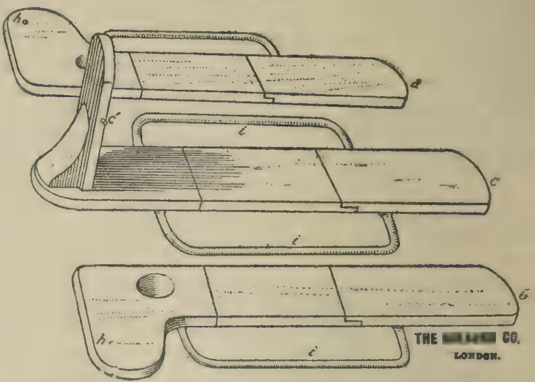
FIG. 1.



Interrupted box splint for compound fracture of the leg (*in situ*).

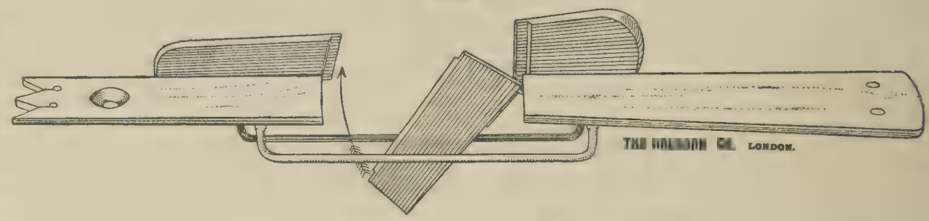
The interrupted long splint for compound fracture of the thigh (Figs. 3 and 4) is a long splint like Liston's, and should be of a similar length. The special feature is that a ledge sufficiently broad to support the limb is fixed at right angles to the lower border of this long splint, extending from the nates to the ankle. The broken limb rests on this and is prevented from "sagging" down at the point of fracture. The long side is interrupted at the site of the wound and the gap is spanned by means of iron hoops or brackets, one being horizontal while the other is vertical, as is shown in the diagram. The ledge is also similarly interrupted at the seat of the wound, but by means of a hinge attached to the side of the upper end it works in and out and bridges over the interruption in the ledge when it is fixed in position. The ends of this interrupted portion of the ledge and the piece which works in and out on the hinge are dovetailed and fit accurately by imbricating with each other when fixed in position. In the diagrams this hinged portion is shown open. The dovetailing is also indicated. These splints are only applicable to cases in which the wound lies at a level corresponding to the openings in them. This need not necessarily restrict their field of usefulness, which latter, to my mind, is fairly comprehensive inasmuch as most fractures occur in those regions of the leg and thigh where the "trap-door" arrangement has been shown. Like all other splints, these also are stocked by the makers in three sizes, so as to meet the requirement of any individual case.

FIG 2.



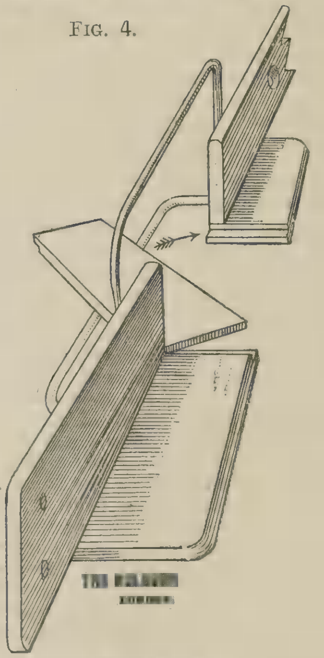
Same as Fig. 1 (in parts).

FIG. 3.



Interrupted long splint for compound fracture of the thigh.

FIG. 4.



Same as Fig. 3.

The splints are made lighter by the woodwork being fenestrated with holes bored through it. When replaced by perforated aluminium sheeting it is rendered both light as well as non-absorbent.

These splints are supplied by the Holborn Surgical Instrument Company, Limited, 26, Thavies Inn, London, E.C. The sketches have been drawn by Mr. James Murray, of Edinburgh, to whom my thanks are due.

HASSAN SUHRAWARDY,
F.R.C.S. Irel.
Medical College Hospital, Calcutta.

LEAGUE OF MERCY.—At the fifteenth annual meeting of the League of Mercy held in St. James's Palace on Dec. 17th under the presidency of Lord Farquhar, it was announced that with the present year the league had completed a collection of over a quarter of a million since its inception. This year £14,000 has been handed over to King Edward's Fund, and £2300 has been distributed among extra-metropolitan hospitals. The King and Queen through Mr. E. W. Wallington expressed their satisfaction on hearing that the league had had so successful a year in spite of difficulties, the amount collected, £18,482, exceeding last year's total. Princess Alexander of Teck made the presentations of the Order of Mercy.

THE LANCET.

LONDON: SATURDAY, DECEMBER 26, 1914.

THE ANNUS MEDICUS 1914.

MEDICINE.

IN dealing with the progress of medicine during the past 12 months attention will first be directed to a consideration of the advances which have been made in the prevention and treatment of infectious diseases.

Tuberculosis.

During the past year further efforts have been made to increase the adequacy of the means for the prevention and treatment of tuberculosis in London. Many schemes have been proposed and a vast amount of time earnestly devoted to a consideration of the methods which seem likely to yield the best results. An inquiry on the subject was instituted by the Charity Organisation Society, who issued a valuable and interesting report. This body has warmly supported from the first the adoption of what is known as the dispensary system, but the Society is convinced that no measure of attack upon the disease has any chance of success unless it begins and ends with the home; unless the patient is followed there, and both he and his surroundings are adequately dealt with, the provision of treatment in institutions or by other means is futile. The Society notes that the dispensary as an isolated unit is manifestly incomplete, and considers that every dispensary should work in close touch with a hospital, so that a consultant's opinion may be available and in order that patients may secure such special diagnosis and treatment as hospitals alone can provide. These are proposals which we entirely endorse. The public health committee presented to the London County Council a complete scheme for the treatment of tuberculosis amongst the uninsured population of the metropolis. The committee stated that it was anxious to encourage the provision of a complete network of dispensaries, and considered that the Council's efforts would be most usefully directed to linking up all the various existing agencies and others which might be created. For the purpose of selecting patients (uninsured) for residential treatment it was recommended that an honorary Tuberculosis Advisory Board should be formed, consisting of representatives from the general and special hospitals and the medical superintendents of certain sanatoriums and dispensaries. A full report on the results obtained by the graduated labour treatment of pulmonary tuberculosis was issued from the Brompton Hospital Sanatorium at Frimley. In order to assist in the diagnosis of tuberculosis researches have been made by several observers as to the value of the complement fixation test. The process is a complicated one, but in the hands of experts and with improved technique the test has made a marked advance.

Dysentery.—Vaccines in Prophylaxis and Treatment.

At the present time special interest attaches to inoculations not only against typhoid but also against paratyphoid fever. The paper published in our columns[1] by Dr. W. BROUGHTON-ALCOCK is therefore worthy of note. The various strains of the causative bacillus were investigated, and some of the results obtained were encouraging. Dr. BROUGHTON-ALCOCK avoided the use of the word vaccine, as he rightly contended that time alone could show the protective value of paratyphoid bacilli inoculations. Dr. F. M. SANDWITH, in delivering the Lettsomian lectures for 1914 before the Medical Society of London, called attention to a disease which has not only a world-wide interest but at the present time a special significance—namely, dysentery, a malady which has hitherto been an inseparable attendant of war in all climates and at all seasons of the year. Dr. SANDWITH gave an interesting résumé of existing knowledge of the disease combined with useful information derived from personal experience. Dealing first with the amœbic variety, he gave a good account of the entamœbæ of the human intestine, and in discussing treatment particularly dwelt on the employment of ipecacuanha and its alkaloids, although the general features suggested by environment were not lost sight of. The prophylactic measures which should be adopted against the bacillary variety were duly discussed, and Dr. SANDWITH remarked that means should be directed, not only against the contamination of drinking water, but also to see that raw vegetables were taken with caution, and he also pointed out that there is reason to believe that flies may act as carriers of bacilli from fæces to food. The discussion which took place in the Medical Section of the Royal Society of Medicine on vaccines from the standpoint of the physician elicited a number of opinions which especially served to emphasise the fact that vaccines, being potent agents capable of doing harm when injudiciously employed, should be given only with a sense of responsibility in conditions in which their use is definitely indicated and confirmed by bacteriological evidence. Amongst other interesting papers published during the year and bearing on the prevention of bacterial diseases was one by Sir ALMROTH E. WRIGHT and three collaborators, Dr. W. PARRY MORGAN, Dr. L. COLEBROOK, and Dr. R. W. DODGSON,[2] on prophylactic inoculation against pneumococcus infections; the conclusion reached was that the vaccines employed by these observers lessened the incidence and the mortality of pneumonia and other conditions produced by the pneumococcus among large collections of natives in the Rand mines, who were highly susceptible to its activity and under conditions favourable to the spread of the infection.

Disorders of the Heart.—Glycosuria.—Lectures Delivered.

Turning now to systemic diseases, researches of disorders of the heart have been extensively carried out, particularly with the aid of the electrocardiograph. Dr. THOMAS LEWIS, in delivering an address at the Pathological Section of the British Medical Association meeting at Aberdeen on the pathology of heart function, discussed some of the disorders of the heart's action which are disturbances of the regular sequence of chamber contraction. He discussed in particular auriculo-ventricular heart-block, premature contractions and allied disorders of the heart's rhythm, and the relation between extrasystolic and physiological beat. He also offered remarks on the rôle of the heart nerves in causing extrasystoles. He said that it had to be acknowledged that the nerves of the heart may play a very significant rôle in producing certain disorders of mechanism, and in attempting to define this rôle more distinctly he was of opinion that there are two questions to which answers may be returned at the present time. Has it been shown the abnormal nerve impulses playing upon a normal heart may be responsible for extrasystoles or the higher types of disorders? He thought that a negative answer must be returned. May nervous impulses playing upon a supersensitive or irritable organ provoke these curious contractions? To this question, Dr. LEWIS maintained, an affirmative answer might be given.

---

[1] THE LANCET, Sept. 19th, 1914, p. 743.
[2] THE LANCET, Jan. 3rd (p. 1) and 10th (p. 87), 1914.

Amongst other subjects which have engrossed the attention of physicians during the past year has been glycosuria. Dr. NESTOR TIRARD in delivering the Bradshaw lecture made the suggestion that some cases of glycosuria depend upon a perversion of pancreatic secretion due to toxic absorption. Dr. W. HALE WHITE chose glycosuria as his subject in delivering an address at a meeting of the Leeds and West Riding Medico-Chirurgical Society. He gave an interesting account of the conditions under which glycosuria appeared, and offered some remarks in the treatment of the disease.

We published in our columns the chief lectures delivered during the year before the Royal College of Physicians of London and other learned bodies. Dr. J. A. ORMEROD delivered the Lumleian lectures, taking as his subject Some Modern Theories concerning Hysteria. Dr. EDWIN GOODALL's Croonian lectures on Problems in the Pathology of Mental Disorders are now appearing in our columns. Dr. FRANK SHUFFLEBOTHAM was the Milroy lecturer, his subject being the Hygienic Aspect of the Coal-mining Industry in the United Kingdom. Owing to the absence on military duty of Dr. GORDON M. HOLMES the Goulstonian lectures were not delivered. Sir R. DOUGLAS POWELL was the Harveian Orator, selecting as his theme Advances in Knowledge Regarding the Circulation and Attributes of the Blood since Harvey's Time.

SURGERY.

Surgery rarely advances *per saltum*, and therefore there is nothing surprising in the fact that the year now drawing to a close has not witnessed any very striking progress in either the theory or practice of surgery. Yet in surgery, as in military operation, there may be many slight advances in various parts of the front, although no striking progress has been made anywhere.

The Operative Treatment of Fractures.

The tendency towards a greater willingness to interfere by operation in fractures has now for some few years manifested itself, and many surgeons have plated fractures which only ten years ago would have been allowed to heal without operation. Yet there are not wanting indications that the zenith of this movement has been passed, and there can be little doubt that treatment by position and splints has replaced a part at least of the plating, which is even yet very strongly advocated by some brilliant surgeons. It is still insisted that if by means of the X rays it can be shown that the fragments are not exactly in position an operation is required; but those who hold this opinion seem to forget that it is the function of the limb that is of importance, while the mere appearance of the bones under X rays avails nothing. It may be urged that one merit of the use of plating is that the circulation of the limb is little interfered with, and stiffness is generally less marked, but the advantages may be more than offset by the fact that in no small proportion of the cases it is found necessary to remove the plate later. This retrogression of the practice of operating on fractures has become noticeable in America also. We would not for a moment wish to underrate the value of operations on fractures in suitable cases; they have a very definite field of utility, but the operation should be more restricted to those cases which need it.

Cholecystectomy v. *Cholecystotomy.*

A few years ago it was customary for the surgeon to treat gall-stones in the gall-bladder by incision of the gall-bladder and removal of the stones, the bladder being drained until the opening closed spontaneously. Sir JOHN BLAND-SUTTON was the first to advocate strongly the removal of the gall-bladder in all cases in which gall-stones were present in it. The arguments which he advanced in support of this opinion were these: In the first place, the absence of a gall-bladder in many animals is a strong indication that it has no very important function; it can hardly be that its presence or absence depends upon the nature of the food, for of two animals feeding naturally on the same food one may have a gall-bladder and the other not. The ox, with a diet consisting almost entirely of grass, possesses a gall-bladder; while the horse, with an identical diet, has no gall-bladder. It is also absent in the rhinoceros, the camel, and the elephant. That it is not essential in man is shown by the fact that those from whom the gall-bladder has been removed appear to suffer from no disability in any way, though too much stress must not be laid on this fact, for many times the spleen has been removed without the patient suffering in any way, and yet no one would venture to say that the spleen has no function. The second argument in favour of cholecystectomy for gall-stones is that there is much reason to think that the cholesterin, which is the main constituent of all gall-stones, is chiefly formed by the mucous membrane of the gall-bladder, and therefore the removal of the gall-bladder will diminish greatly the chance of any recurrence of the disease. There is yet a third reason in favour of the complete removal of the gall-bladder, and that is the fact that the occurrence of malignant disease of that viscus seems to be specially influenced by the presence of gall-stones; this is the greatest and most important argument of all, and in itself would be sufficient to warrant the routine removal of the gall-bladder. There are, however, cases in which when the abdomen is opened the gall-bladder is found surrounded by adhesions, and if the patient is old and feeble, the operation of cholecystectomy might be accompanied by more risk than the benefit accruing from it would be worth. The present position seems to be then that whenever an operation is performed for gall-stones it is always advisable to remove the gall-bladder, unless unfavourable conditions are present. Before, however, the surgeon removes the gall-bladder he must assure himself that the common bile-duct is pervious; if it is blocked by a stone the stone must be removed, but the duct may be closed by cicatricial tissue; in such a case it is clear that it will be necessary to make an anastomosis between the gall-bladder and the duodenum, so that any question of the removal of the gall-bladder cannot be considered.

Aseptic Surgery.

The epoch-making discoveries of Lord LISTER in the prevention of septic diseases needed a few years to be fully appreciated, but at last, it may be said, they were universally received; even then, however, many of those who carried out "antiseptic surgery" did so in an unintelligent manner, thinking that by antiseptic surgery was meant the observance of a certain routine and not the practical application of a principle. Nay, more, some appeared to imagine that antiseptic surgery meant nothing more than the lavish employment of carbolic acid in season and out of season, but without that attention to general cleanliness which had formed so important a part of what LISTER had taught.

It was only natural that there should have been a reaction against what was called "Listerism" when it was recognised that some of the methods employed by LISTER were unnecessary, when it was discovered that an abdominal section could heal without any sepsis, either in the peritoneum or in the abdominal wall, even though the carbolic spray had not been used. In the same way it came to be recognised that some other details of Listerian practice were unnecessary or could be usefully modified; these discoveries were thought by some to lessen the value of all LISTER'S teaching, though, indeed, no one was more ready to modify and improve his methods of practice than LISTER himself. He discarded the spray, devised new and less irritating antiseptics for the dressings he employed, and his results were equally good; but the critics of LISTER appeared always to forget these things. There is indeed much to be said in favour of some of the methods of aseptic surgery, and the excellent results which follow its practice show what may be done by its aid, but it appears often to be forgotten that aseptic surgery employs antiseptics. The skin of the patient and the hands of the surgeon both need sterilising so far as that is possible, and up to the present no other method has been devised for doing this than the use of antiseptic substances. Even the instruments need sterilising, and the employment of heat for this purpose instead of carbolic acid does not prevent the process from being antiseptic. The results obtained by LISTER himself have never been surpassed, and perfect results so far as relates to sepsis will always be attainable by any surgeon who will follow LISTER'S principles, though not necessarily by copying blindly the details of his practice.

OBSTETRICS AND GYNÆCOLOGY.

In the Arris and Gale lectures Dr. F. WOOD JONES[1] discussed the morphology of the external genitalia and brought forward interesting evidence in favour of the view that there are two main types of development and two main types of resulting external genitalia; that all mammals may be placed in the one group or the other; and that an examination of the adult genitalia will generally, and an examination of the embryonic stages will always, reveal definitely into which group a particular species falls.

A discussion on the need for research in antenatal pathology took place at the Obstetrical Section of the Royal Society of Medicine,[2] and a good deal of interest has been aroused by the publication of the scheme of the Local Government Board for the administration of maternity and child welfare centres, for which it has obtained a grant from Parliament of £12,000. A synopsis issued by the Board sets out the main outlines of the scheme, which includes antenatal, natal, and postnatal treatment of mothers and the welfare of the children from birth until the time they are entered on a school register. The scheme has many excellent features and by loyal coöperation between maternity centres, lying-in hospitals, and the local authorities should be productive of much good.

Investigations regarding Pregnancy.

The duration of pregnancy has more than a theoretical interest. Dr. BERRY HART,[3] from a biometric analysis of insemination labour curves, points out that in the statistics published with regard to cattle this method of analysis shows that the average duration of pregnancy is 283 days with a probable error of plus or minus six days. In the human subject the date of labour reckoned from the last day of menstruation should be 278 days, plus or minus seven days, but the most probable duration is 277·93, or 278·63 days.

It has been suggested recently that it might be possible to demonstrate the presence of the defensive ferments which ABDERHALDEN has shown to occur in the blood in pregnancy by means of inoculation on the analogy of the tuberculin reaction of VON PIRQUET. ENGELHORN and WINTZ[4] have carried out some experiments using a placental extract they term "placentin." By the injection of this substance hypodermically they claim that in the pregnant woman a positive reaction is obtained consisting of inflammatory swelling and redness of the inoculated areas with a light brown staining round them. A negative result is said to be obtained shortly after parturition. The results of their work are very interesting, but further investigations are required before any conclusion can be come to as to the value of this method.

In a paper on Nitrogen Metabolism during Pregnancy based upon a series of investigations on the Ammonia and Total Nitrogen Output in the Urine, read before the British Medical Association, Dr. H. LEITH MURRAY[5] commented upon the small amount of work done in the majority of lying-in hospitals in the examination of the urine. He was convinced of the great importance of these investigations, and demonstrated three simple quantitative tests which could be employed by a comparatively inexperienced worker in a clinical laboratory. It is becoming increasingly evident that, if our knowledge of the so-called toxæmia of pregnancy is to increase, a large amount of work must be done in this direction. Unfortunately, in this country there are very few lying-in institutions equipped either with the workers or the laboratories for them to work in, and until the pressing necessity for the provision of pathological laboratories in which investigations can be carried on is recognised in conjunction with clinical observations at the bedside, we can hope for very little progress in our knowledge.

Pubiotomy.—Treatment of Fibromyomata.

The merits and demerits of pubiotomy are still matters of dispute. In a discussion on the Management of Pregnancy and Labour in a Contracted Pelvis, at the British Medical Association meeting, JELLETT and HASTINGS TWEEDY[6] advocated pubiotomy, and FRANK, of Cologne, of symphysiotomy in what is often termed the second degree of contracted pelvis—viz., that in which the conjugate diameter measures from 2¾–3¼ inches. SHANNON, of Glasgow, pointed out that neither of the operations found much favour in Professor MUNRO KERR'S clinic, and KYNOCH and OLIPHANT NICHOLSON preferred rather the induction of premature labour. It is interesting to note the popularity of pubiotomy with certain members of the Dublin school, as so far it has not made much progress in England, and apparently is not very enthusiastically supported in Scotland.

The discussion on the treatment of fibromyomata of the uterus which took place at the same meeting was noteworthy for the almost unanimous condemnation by the different speakers of radiotherapy as a means of treating such tumours. At the same time none of them produced any evidence that they had had any practical experience of this method, so that their criticisms do not carry much weight. In view of the striking results which are said to have been obtained by workers on the continent we must wait for the published results of those gynæcologists in this country who are at present employing X rays in the treatment of fibroids before forming a final judgment on the subject. Several of the speakers were in favour of removing both ovaries with the uterus, and it is surprising to find what little importance they appear to attach to the mental effect which the knowledge that she had been "spayed" must have upon the ordinary woman.

Uterine Hæmorrhage.—Cancer of Uterus.

Uterine hæmorrhage formed the subject of a Hunterian lecture by Mr. BECKWITH WHITEHOUSE,[7] and an important contribution on the same subject was made to the Obstetrical Section of the Royal Society of Medicine by Professor BRIGGS and Dr. R. A. HENDRY. Mr. WHITEHOUSE suggests that three factors are concerned in the control of normal menstrual hæmorrhage—viz., the effect of uterine contractions, the action of a hormone or hormones producing capillary dilatation in utero, and the biochemical function of the endometrium. His lecture will well repay reading. Professor BRIGGS and Dr. HENDRY bring forward evidence to show that it is doubtful if there is any causal relationship between so-called fibrosis uteri and uterine hæmorrhage.

Interesting and important papers on the Treatment of Cancer of the Uterus have appeared during the past year by Dr. THOMAS WILSON,[8] who summarises his operative results, and Dr. J. F. PERCY,[9] who read before the Clinical Congress of Surgeons of North America a paper on the Treatment of Inoperable Carcinoma by the Application of Heat. The basic idea of this treatment, which is carried out by means of an electrical heating iron and water cooled speculum, is not cauterisation but the production and dissemination of heat in the gross primary mass of cancer.

OPHTHALMOLOGY.

An effect of the war has been to prevent the meeting of the Twelfth International Congress of Ophthalmology, which should have met at Petrograd in August, and to stop the flow of ophthalmic journals and literature from practically the whole of the Continent. The loss due to the failure of the congress is limited to the discussions, for the original papers have been printed and distributed to the members. Amongst them the report on the etiology of trachoma by Professor AXENFELD forms a volume of 200 pages, and is a very valuable contribution. As might be expected, there are many other papers on trachoma, a subject likely to be full of interest to our Russian colleagues. Otherwise the papers are rather disappointing, and English contributors are conspicuous by their paucity, Lieutenant-Colonel R. H. ELLIOT and Dr. KARL GROSSMANN alone appearing in the list. The former deals with his trephining operation for glaucoma, a subject which he has repeatedly discussed during the past year elsewhere, notably at the Congress of American Surgeons in London. This operation has also been exhaustively discussed by many other writers, English, American, and German, and whilst its great utility is freely acknowledged, some considerable drawbacks, such as late infection, have come to light. It still, however, holds its own as the operation of election in chronic glaucoma, though opinions differ as to its use in acute glaucoma.

The reports of the British and American Ophthalmological Societies for this year are particularly noteworthy, and contain some very admirable communications. The second meeting of the British Society under the new régime as an annual congress was a great success. Professor UHTHOFF'S Bowman Lecture on ophthalmic experiences and considerations on the surgery of cerebral tumours and tower skull was excellent and full of material of equal value to physicians, especially neurologists, general surgeons, and ophthalmologists. It serves to remind us now of the disastrous blow which Germany has struck against international science, a blow from which it will not recover for many years. The President, Mr. RICHARDSON CROSS'S address was a review of the history of the society, with many discursive remarks of much interest. The discussion on post-operative complications of cataract extractions was unusually good and merits special consideration. It was opened by Mr. E. TREACHER COLLINS, who dealt with the anatomical and pathological aspects of the question, illustrating his remarks by a valuable series of photographs. Lieutenant-Colonel H. HERBERT dealt with the clinical aspects; Mr. S. H. BROWNING, bacteriologist to Moorfields Eye Hospital, with the bacteriology; and Mr. C. KILLICK with his own experiences. The ensuing discussion elicited many important observations from Professor LANDOLT, Professor STRAUB, Lieutenant-Colonel ELLIOT, and others. Amongst the many good papers read at the meeting the following deserve special mention: Flat Sarcoma of the Choroid, by Mr. R. AFFLECK GREEVES and Dr. GORDON HOLMES; Homonymous Hemianopsia without other Evidence of Organic Disease, by Mr. F. RICHARDSON CROSS; Optic Neuritis and Myelitis, by Mr. CHARLES GOULDEN; Papillœdema in Disseminated Sclerosis, by Mr. LESLIE PATON; and Diseases of the Eye in Animals, by Mr. M. S. MAYOU.

The American Ophthalmological Society also record some papers of outstanding merit. We may mention particularly those on Sclero-corneal Trephining, by Dr. A. QUACKENBOSS and Dr. MYLES STANDISH; Extractions of Cataract in the Capsule, by Dr. ARNOLD KNAPP; Cranial Deformity associated with Ocular Changes, by Dr. T. B. HOLLOWAY; the Pathology of the Corneal Section, by Dr. F. TOOKE; and Psammosarcoma of the Orbit, by Dr. G. E. DE SCHWEINITZ. Dr. H. F. HANSELL and Dr. C. E. G. SHANNON re-advocate preliminary capsulotomy in the operation for the extraction of immature cataract, a procedure likely to find little favour with most ophthalmologists. It may be noted that Lieutenant-Colonel HENRY SMITH'S intracapsular extraction, which has never been adopted in this country, appears to be losing support in the United States, where it had warm advocates.

[7] THE LANCET, March 28th (p. 877) and April 4th (p. 951), 1914.
[8] THE LANCET, August 1st, 1914, p. 318.
[9] THE LANCET, August 1st, 1914, p. 309.

The American Ophthalmological Society has thoroughly discussed the question of instituting a diploma in ophthalmology. If it be admitted that such a diploma is desirable—a moot point—it would be difficult to devise a better scheme than that set forth in the society's report. Special stress may be laid upon the recommendation that *two years* shall be devoted to the course. We believe that this far exceeds the time demanded by the Oxford authorities for their diploma, but most ophthalmologists will agree that it is not too long, and that the examination should be of such a searching character, both in the scientific foundations and the clinical and practical details, as shall ensure a *cachet* which is no mere sinecure.

The contributions to the Ophthalmological Section of the Royal Society of Medicine have been above the average, but as they have already been reported in abstract in THE LANCET it is unnecessary to refer to them in detail. Special attention may be drawn to the very instructive discussion on nystagmus by this section combined with the Neurological Section, and to that on the use of salvarsan in ophthalmic practice.

The *Royal London Ophthalmic Hospital Reports* are now edited by Mr. J. HERBERT PARSONS in place of Mr. WILLIAM LANG, who has been appointed a consulting surgeon to the hospital. It still publishes only original communications, and these are well up to the average. The papers by the late Mr. E. NETTLESHIP and by Mr. C. H. USHER on heredity are important not only to ophthalmologists, but to scientists in general. It may be mentioned that this journal does not receive the support from ophthalmologists which it merits.

There are two subjects of ophthalmic interest which are occupying the attention of Departmental Committees of the Home Office and Board of Education respectively. That of the Home Office is considering the lighting of factories, and has been engaged in a large amount of arduous spade-work in collecting data. That of the Board of Education is dealing with "blindness" as a disablement meriting pecuniary assistance. One of its duties will be to determine the nature and amount of the deprivation of the visual faculty which entails loss of wage-earning capacity.

NEUROLOGY.

If there has been, perhaps, no outstanding neurological contribution during the year, this branch of medicine, nevertheless, continues to be the object of research of an ever-increasing number of investigators.

Poliomyelitis has not, apparently, been quite so prevalent this year as last year. Much experimental work, however, has been done on the disease. The virus has been shown not to pass readily from the blood to the cerebro-spinal fluid, *viâ* the choroid plexus, unless the latter is injured. If the virus fails to reach the central nervous system it is destroyed in the body. It has been established, also, that in its transit the virus can be neutralised by intraspinous injection of immune serum, and paralysis, experimentally at least, may thus be averted (FLEXNER and AMOSS).

The problem of syphilis of the nervous system and its treatment bulks more largely than ever in the literature. The gist of numerous contributions on the question of the value of treatment by intraspinous salvarsanised serum may be given as follows: very fair results have been obtained in cerebro-spinal syphilis, in tabes the method is less useful, while in general paralysis its value is problematical. Further investigation is required before importance can be attached to the intraventricular route (OPPENHEIM, LEGENDRE, PILSBURY, AYER, RIGGS and HAMMES, STEWART, CAMPBELL, BALLANCE, and others).

In the matter of diagnosis continued attention has been paid to the cerebro-spinal fluid. The cell count often gives warning of a meningeal affection earlier than the Wassermann reaction, while, after treatment, it also often gives the earliest indication of improvement. The substance which produces the pleocytosis is distinct from the Wassermann substance (DONALD, MCINTOSH, FILDES, HEAD, and FEARNSIDES). Lange's colloidal gold reaction in the cerebro-spinal fluid is said to be a more delicate test for syphilis than either the Wassermann reaction or the cell count (LEE and HINTON).

A vast amount of research has centred on the relations of the ductless glands to the nervous system. It is now thought that many of the symptoms associated with lesions of the hypophysis are in reality due to involvement of nerve tissue in the neighbouring tuber cinereum and its vicinity (CAMUS and ROUSSY). By experimental testing of lipoids obtained from various glands more definite results are procured than by the inexact methods of extirpation (ISCOVESCO). There seems to be a definite relation between the adrenals and the lymphatic system (CROWE and WISLOCKI). Myasthenia gravis is in all probability a disease of the ductless glands (STERN).

The sympathetic system has been the object of prolonged researches. Much attention has been given to the oculo-cardiac reflex. In many persons a normal slowing of the radial pulse by 5 or 6 beats a minute occurs when the eyeballs are pressed back into the orbits (ASCHNER). This is the positive reflex; if tachycardia results the reflex is inverted. The anatomical path is by the fifth nerve, medulla, and vagus. The reflex is of considerable physiological interest, and probably of clinical importance, as giving an indication of the state of tonus of the autonomic system. The reflex is abolished after injection of atropine. Respiratory phenomena may also be produced by ocular pressure. In some cases the heart can be stopped. The reflex is exaggerated in epilepsy. It is often abolished in syphilis. It is almost always lost in paralysis agitans. In yawning, sneezing, and obstinate hiccough ocular compression has a definitely regulating effect (LOEPER and WEIL, LESIEUR, VERNET and PETZETAKIS, MONGEOT, DUFOUR and LEGRAS, and others).

ELECTROTHERAPEUTICS AND RADIOLOGY.

The subject of electrotherapeutics seems to have been undergoing a period of transition during recent years, the effects of which can now be traced with some accuracy. This has been brought about by the revival of cataphoresis, or ionic medication as it is now called. The study of this method has helped us in no small degree to realise that the effects of electricity on living tissues are either thermic or ionic. Recognition of this has led to a better understanding and more scientific methods. Of ionic medication we have heard much during recent years, and it deserves the position it has attained in therapeutics. The thermic effects of electricity are best exemplified in the use of low-tension high-frequency currents—diathermy. This is the only means at present known of raising the temperature of the subcutaneous tissues, and the effects are being carefully studied. A series of articles appearing in the *Archives of the Roentgen Ray*, by Dr. E. P. CUMBERBATCH,[1] throws a considerable light on this interesting subject. LEDUC[2] has shown that the application of the constant current to the brain is not only a safe procedure but one that has great therapeutic possibilities.

Few branches of medicine have been more profoundly influenced by the outbreak of the present war than that of X ray diagnosis. The study of the application of the X ray in the elucidation of internal disorders has given way to that of the effects of projectiles and their localisation. What used to be a very occasional feature of civil practice has suddenly become one of the first importance. Shrapnel wounds form the greater number, and owing to the dirt carried in with the fragments such wounds are almost invariably septic; thus the prompt localisation and removal of the fragments are needed, and prompt removal depends on accurate localisation. We are indebted to Sir J. MACKENZIE DAVIDSON for very accurate methods of doing this, and articles by other writers are to be found in most of the medical papers.[3] A very simple and expeditious method has been worked out by HAMPSON,[4] and an X ray table is now available with which this method can be carried out with convenience, accuracy, and rapidity.

The most important novelty brought out is a new form of X ray tube, due to Dr. COOLIDGE of America.[5] The essential feature is that it is possible to adjust it for any desired degree of radiation or current ever likely to be required, and it will remain in exactly the same condition more or less indefinitely. It promises to be a most important advance in radiology. As regards the use of the X rays and radium in therapeutics there is nothing very new to report. The present position of radium therapeutics can be best appreciated in the last report of the Radium Institute.[6] Important developments have been made, but as this report points out, we are scarcely any, if at all, nearer a cure of inoperable cases of malignant disease.

The use of the X rays in therapeutics continues unabated and even increases. The absence of a perfect method of measurement is a drawback, but to the experienced radiologist this is not so serious as it might appear. The use of the rays in the treatment of certain cases of uterine fibroids is meeting with considerable favour, but some time must yet elapse before we are in a position to estimate with any accuracy the value of the method.

DERMATOLOGY.

Pellagra is no new disease, for it was first described 150 years ago by Casal, and it has been widely known for many years, especially in Italy; but its importance as regards this country is of very modern origin, for it has not been recognised in the British Isles until the early years of this century. It is a general disease, but the digestive, the nervous, and the cutaneous systems are most involved; and the affection is of especial interest to dermatologists, as the skin manifestations appear early and may materially assist in diagnosis; in fact, Caszellani has suggested in doubtful cases placing the patient in the sunshine to evoke the rash. The disease is probably more common here than was thought, and cases have been found in asylums the origin of whose mental condition had been quite unsuspected. As to its etiology we are in much doubt; not so long ago it was almost universally accepted that it resulted from maize, but recent researches have thrown great doubt on this view of its origin, and opinion seems to be tending to the view that it is microbic in origin, the organism being perhaps ultramicroscopic. As dermatologists will generally have the opportunity of seeing cases of pellagra in a comparatively early stage, it is important that they should be in a position to recognise it readily, for any treatment to be effective must be early. The early erythema, the eczematous condition which follows, and the roughened pigmented condition which results are generally easily recognisable if the dermatologist is alive to the possibility of the occurrence of pellagra.

An event of no little importance during the year was the discussion on mycosis fungoides which was held in the Dermatological Section of the Royal Society of Medicine in May and June. A large number of the members of the section spoke, and divers views were enunciated. Nothing which was of general acceptance was elicited as to the etiology, but several speakers expressed the opinion that it was parasitic. Various analogies to other diseases were suggested, but the general opinion seemed to be that it was a disease *sui generis*. The histology was shown to be of extreme value in diagnosis in obscure cases. As to the treatment, while all agreed that the X rays were of great value, most of those present had never seen any complete and permanent cure.

TROPICAL AND EXOTIC DISEASES.

The closing year has witnessed further advances in our knowledge of tropical and exotic diseases. As each year passes the number of investigators and observers increases in this branch of medicine, so that the combined efforts becomes annually greater in the unravelling of the mysteries associated with the causation and prevention of these serious maladies. In other lands beside our own schools are being established for instruction in tropical medicine, so that it is comparatively rare nowadays to meet in the tropics with a newly arrived practitioner who has not received some sort of special training as regards the diseases peculiar to warm climates. Such trained men are perfectly capable of adding much to the general stock of knowledge respecting tropical and exotic diseases. Great advances may therefore be anticipated in the near future.

[6] THE LANCET, May 23rd, 1914.

The London School of Tropical Medicine, with aid from the Board of Education and from Mr. Austen Chamberlain's Fund, has been enabled to commence a systematic course of instruction in tropical sanitation and hygiene, a most important addition to the curriculum of the school, and one that is likely to produce far-reaching results in our colonies and dependencies, where the application of the principles of sanitary science is quite as necessary as it is at home, but where it has not hitherto, in our opinion, received sufficient attention. Early in the year this school despatched an expedition to the Far East, comprising Dr. R. T. LEIPER, Surgeon E. L. ATKINSON, R.N., and Mr. CHERRY-GARRARD, to study the mode of spread of trematode disease, particularly bilharziasias. The expedition landed at Shanghai and proceeded up the Yangtse river into Central China. On the homeward journey the expedition proposed to visit Sumatra to inquire into the ravages caused there by ankylostomiasis in certain tea and rubber plantations. The cost of this expedition was to be borne partly by the Colonial Office and partly by the United States Rubber Company. In the early summer of 1914 it was decided by the Liverpool School of Tropical Medicine to establish a permanent research laboratory on the West Coast of Africa, and Sierra Leone was chosen as a suitable centre from which expeditions might be despatched from time to time to other regions in tropical Africa. In November Dr. WARRINGTON YORKE, the Walter Myers professor of parasitology in the University of Liverpool, and Dr. B. BLACKLOCK, director of the Runcorn Research Laboratory, left this country for Sierra Leone to investigate the biting insects which are associated with tropical diseases in that part of the Dark Continent, and also to report upon a suitable site for the proposed "Sir Alfred Jones Laboratory" in Sierra Leone.

In 1914 a number of valuable papers were read before the London Society of Tropical Medicine and Hygiene, and many members from all parts of the world at one or another time have taken part in the discussions. The new president of this society, Sir RICHARD HAVELOCK CHARLES, G.C.V.O., is worthily maintaining the high standard of efficiency set by his three distinguished predecessors—namely, Sir PATRICK MANSON, Sir RONALD ROSS, and Sir WILLIAM LEISHMAN.

Tropical and Exotic Diseases in India.

In India, which by itself constitutes a wide field for observation and research in tropical and exotic diseases, progress continued to be made during the year, evidence of which is to be found in the establishment of a new school of tropical medicine in Calcutta. The foundation-stone was laid in February by Lord CARMICHAEL, Governor of Bengal; the cost of the buildings is estimated at 11½ lakhs of rupees (£76,667), half of which is being contributed by the Indian Government. A considerable amount of money has also been raised by private subscription through the efforts of Lieutenant-Colonel Sir LEONARD ROGERS, I.M.S., who acts as honorary secretary to the endowment fund. It is expected that this school will commence operations next summer, and diplomas in tropical medicine will be granted after examination. There will be a full staff of professors giving their whole time to the duties. A number of researches are being carried out in India in the various laboratories at Kasauli, Parel, Madras, and Coonoor, as well as in the Imperial Bacteriological Laboratory at Muktesar, which is devoted to the study of epizootics. We are glad to learn that the Director-General of the Indian Medical Service, Sir C. PARDEY LUKIS, K.C.S.I., whose tenure of office would have in ordinary circumstances ceased at the end of 1914, has had his term extended to the end of 1916. This extension is the more important since the Government of India has entered of late upon a progressive sanitary policy which is likely to have a far-reaching influence upon the health of the natives of India; it is imperative, therefore, that there should be no break in the direction of the operations now being carried out by the Indian Medical Service for this purpose.

Cholera.

Major E. D. W. GREIG, I.M.S., has been for some time making special investigations on the subject of cholera, and in the *Indian Journal of Medical Research* some of his very interesting results have been published. These included inquiry into the invasion of the tissues by the cholera vibrio, and the lesions of the gall-bladder and biliary passages in that disease. Major GREIG's studies have supplied a scientific explanation of the mechanism of the production of cholera carriers. In connexion with the subject of cholera it may be mentioned that Dr. RENAULT, Director of the Sanitary Service of French India, has reported good results from the treatment of this disease by hypodermic injections of emetine, the method being suggested to him by the success obtained by Sir LEONARD ROGERS with the same remedy in amœbic dysentery. Evidence has accumulated showing that the spread of cholera in India is associated in large part with the Hindu pilgrimages and bathing fairs, at which large numbers of natives assemble together under very unfavourable conditions, and where after an outbreak convalescents and chronic carriers convey the infection to distant parts of India. The sanitation of pilgrimages is therefore receiving increased attention.

Leishmaniasis.

Leishmaniasis continues to attract considerable notice in India as well as elsewhere, and special investigations are at present being carried out in Assam, the chief endemic centre of the disease, by Captain F. P. MACKIE, I.M.S., and Dr. V. T. KORKE. Captain W. S. PATTON, I.M.S., is continuing his investigation of this disease under the auspices of the Madras Government. Dr. R. ROW, of Bombay, has found leishmania donovani in the circulating blood of a kala-azar patient. This observer has also conducted a series of experiments on monkeys with L. donovani and L. tropica, and as the results were very similar he thinks that this may be regarded as a proof of the identity of these two organisms. In Europe cases of leishmaniasis continue to be found in many of the larger towns on the Mediterranean littoral; and in Marseilles Dr. PRINGAULT has found signs of the disease in the bone marrow of stray dogs taken from the streets. At the annual meeting of the British Medical Association at Aberdeen in July, Fleet-Surgeon BASSETT-SMITH, C.B., R.N., read a paper summarising our present knowledge on the subject of leishmaniasis.

Trypanosomiasis.

Trypanosomiasis is still being investigated in tropical Africa, and reports have been published during the year by the Royal Society's Commission, which includes Surgeon-General Sir DAVID BRUCE, C.B., A.M.S., Major A. E. HAMERTON, R.A.M.C., Captain D. P. WATSON, R.A.M.C., and Lady BRUCE. Among other work experiments have been carried out by them with laboratory-bred tsetse flies, G. morsitans, G. brevipalpis, and G. palpalis, as regards the transmission of various strains of trypanosomes. Dr. E. TEICHMANN, in German East Africa, has also been investigating the same subject, and has come to the conclusion that it would be correct to say that all species of glossina are capable of transmitting all species of trypanosomes provided suitable conditions are present. Surgeon-General Sir DAVID BRUCE regards T. brucei and T. rhodesiense as one and the same organism. He has recently proposed a new system of classification of African trypanosomes pathogenic to man and animals. With reference to the vexed question whether big game in Africa act as reservoirs of the sleeping sickness infection, Mr. RUPERT W. JACK, the entomologist for Southern Rhodesia, states that he has collected evidence which appears to favour strongly the view that there is a vital association between the prevalence of big game and the continuation or increase of Glossina morsitans in S. Rhodesia. The tsetse fly has disappeared from localities where big game has been destroyed by settlers in the process of opening up new country.

Yellow Fever.

Yellow fever has been exercising the minds of many epidemiologists of late, and important investigations have been carried out by a number of observers during the year. The Yellow Fever Commission (West Africa), appointed by the Secretary of State for the Colonies, has presented two reports, and a third is expected shortly. Several experts have utilised the opportunity afforded by an outbreak of the disease in Southern Nigeria to search for the specific parasite of the malady. Dr. J. W. SCOTT MACFIE and Dr. J. E. L. JOHNSON claim to have found the so-called "yellow fever bodies," to which the discoverer, Dr. H. SEIDELIN, has given the name of paraplasma flavigenum, in the blood of practically all the cases in and about Lagos diagnosed clinically as yellow fever. They also found the same bodies in the blood of some native dogs, and were able to transmit the organism through a series of guinea-pigs and other animals. Their work has been confirmed by Dr. SEIDELIN, who was despatched by the Commission to Lagos; this expert, along with Dr. A. CONNAL, also performed many animal experiments and examined many blood smears from human beings. Dr. SEIDELIN contends that, as in other infections, yellow fever may be spread by human carriers. These findings are now being carefully examined by the members of the West African Commission, who will, it is anticipated, give a definite pronouncement on them in their next report. Dr. A. BALFOUR has recently visited Trinidad, where there had been an outbreak of yellow fever, and hearing that among the negro population of the island there is a strong belief that an undue mortality among the red howler monkeys, which abound in the woods of the island, always precedes an epidemic of yellow fever, made some inquiries on the subject on the spot. His opinion is that it is quite possible that the red howler monkey in Trinidad may serve as a reservoir of the virus, from which it may be transferred by the stegomyia mosquito to man. The value of ducks as destroyers of the larvæ of stegomyia has also been pointed out.

Sprue.

Sprue has long puzzled the etiologist, but the researches of Dr. P. H. BAHR in Ceylon seem to have settled the problem. He identifies the organisms found in sprue with the thrush fungus, monilia albicans. Dr. ALDO CASTELLANI has contributed also to our knowledge of the hyphomycetes found in sprue. He believes that there is a plurality of species of the sprue fungi and classed under the name of M. albicans. Dr. CASTELLANI, who has been a frequent writer on tropical diseases, and who has carried out much research work in Ceylon, has just been appointed professor of tropical medicine in the University of Naples and director of the Royal Clinic for Tropical Diseases in that city. He leaves Ceylon to take up his new post early in the coming year.

Research Work by American Experts.

Much valuable work has been done by the American medical officers stationed in the Philippine Islands, and their scientific and practical contributions published in the *Philippine Journal of Tropical Medicine* have often been mentioned in the columns of THE LANCET, particularly as regards beri-beri, amœbic dysentery, plague, and other maladies. In the same way the medical experts from the United States stationed in the Panama Canal Zone, in addition to other original work, continue to demonstrate that modern scientific methods can reduce greatly the ravages of tropical diseases and render it possible for the white races to occupy and carry out their businesses in hot climates formerly regarded as extremely unhealthy for foreigners. In this connexion it may be mentioned that Surgeon-General W. C. GORGAS, who has directed sanitary measures in the Canal Zone, along with his two assistants, Dr. T. S. DARLING and Major R. E. NOBLE, were entertained at a public banquet by the medical profession in London on March 23rd, Sir THOMAS BARLOW, President of the Royal College of Physicians, being in the chair. The Annual International Sanitary Conference of the American Republics was held in December, 1914, at Montevideo, the capital of Uruguay. These annual conferences serve the very useful purpose of spreading the knowledge of sanitation and the modern prophylaxis of tropical diseases. In many places in South America an anti-mosquito campaign has been carried out of late with beneficial results.

Ankylostomiasis.

In the United States the subject of ankylostomiasis has been receiving considerable attention. An International Commission has been appointed as an offshoot of the Rockefeller Foundation, which was established to continue in foreign countries against hookworm disease the campaign which had been so successful in the United States. The foreign branch of this Commission is at present confining its operations chiefly to Egypt, where half of the expenses of the campaign in that worm-infested land are being defrayed by it and the other half by the Egyptian Government. Dr. A. F. MACCALLAN, who is directing the ankylostomiasis operations in Egypt, gave an account of the work being done in that country to the Section of Tropical Medicine at the annual meeting of the British Medical Association.

Pellagra.

With regard to pellagra the Thompson-McFadden Commission of the New York Post-Graduate Medical School continues its labours, and some officers of the United States Public Health Service, under the direction of Dr. JOSEPH GOLDBERGER, are carrying out an official inquiry on the subject, more particularly as to the incidence of the disease in public institutions in the Southern States and its connexion, if any, with institutional dietaries. Captain EDWARD B. VEDDER, of the Medical Corps of the United States Army, well known for his researches on beri-beri, has also contributed to the literature of pellagra in the *American Journal of Tropical Diseases* during the present year.

PUBLIC HEALTH.

At the end of this year considerations of public health centre on the position which has been brought about by the war and all that the war has entailed. Below we refer to a few of the important matters, some of which now seem curiously remote, which were occupying attention in this country in the time of peace, but the first portion of the space at our disposal must relate to events after the fateful early days of August.

Health of the Expeditionary Force.

So far our public health record has been good beyond anticipation. The British Expeditionary Force has suffered very little from epidemic disease. Enteric fever, so much dreaded, has been reported to be prevalent in various places near the seat of operations in the west, particularly among Belgian troops brought to Calais in November. But up to the end of this month its incidence on the British forces in France and Belgium has been relatively insignificant, amounting to less than 150 cases[1] altogether, a satisfactory result to be attributed in very large measure to the strenuous efforts of all branches of the Royal Army Medical Corps, and the action taken to obtain systematic inoculation of our soldiers with antityphoid vaccine. Cholera, which was reported as early as October among the forces operating in the South of Poland and Galicia, has fortunately not reached the Allied lines on the west, though its presence in Antwerp was rumoured more than a month ago, and attributed to the transfer of some of the enemies forces from the east. We have as yet no intelligence of small-pox or of any severe prevalence of dysentery in the western force. While these and other epidemic diseases may soon have to be encountered by our army abroad, it is believed that the present strategic position is giving time and opportunity for the organisation of measures of prevention and treatment in a way which was impossible in the earlier stages of the war. This consideration applies not only to personally communicable illnesses, but also to diseases resulting from exposure to cold, wet, and vermin, which are necessarily of enormous importance to the efficiency of the army. We look to the future with hopefulness, and with confidence in the men by whom this vital work is being so strenuously undertaken, both in the army and in the navy.

Sanitary Problems following Mobilisation.

At home the outbreak of the war led naturally to anticipations of the early prevalence of disease following general privation and unemployment. Fortunately, neither those conditions nor their consequences have arisen, and the general health of the population at home during the last five months has remained good. Some problems calling for special precautions by sanitary authorities and others concerned arose in connexion with the influx of Belgian refugees, many of whom were completely destitute,[2] but so far as we are aware no serious importation of infectious disease has followed the action taken by the nation in this matter. The ordinary routine of public health administration has naturally been considerably disturbed; many medical officers of health were mobilised with the Territorial Force, or have since joined the new armies, and have consequently been removed from their districts. Others have had to work with greatly reduced staff, and in most parts of the country temporary arrangements and appointments have been necessary to carry on the ordinary work of medical officers of health, medical inspectors of schools and factories, and the management of isolation hospitals, tuberculosis and Poor-law institutions. On mobilisation the relation of local public health authorities and their officers to the military units in their areas at once claimed attention, and in many places active measures were taken to assist the military authorities in matters of local hygiene. The need for more systematic action was, however, soon apparent. The steps taken jointly by the War Office and Local Government Board in this matter were fully referred to in recent articles,[3] and the importance of an official system of coöperation has since been increased by the augmentation of the new armies and the huge scale on which billeting of troops on the civil population has now been carried out. It is to be hoped that the arrangements already made will be further developed and utilised to the full.

Sanitary Condition of Home Forces.

For the sanitary supervision of troops in this country the Army Medical Service already had at their disposal the services of men familiar with military hygiene as regular or Territorial sanitary officers, and other public health experts have since been appointed from the civilian service for duty with the different divisions of the home forces. This service is as necessary and important as that of any other branch of the army; it has already done most valuable work, and its strength could probably be added to with advantage. A central committee, comprising civil and military members, was also appointed in November to advise the War Office on sanitary matters. The London sanitary companies of the Territorial Force have been utilised in the new armies and their strength increased. Inoculation against enteric fever has been successfully pressed among the troops at home, though not without some opposition from bodies which endeavour to create prejudice against all such methods of prophylaxis. Verminous conditions have in some places given considerable trouble, and in a few camps the problem of venereal disease has threatened to become serious.[4] The occurrence of epidemic measles among regiments recruited in the more isolated parts of the country, especially those from the Highlands and Islands, is also noteworthy. Piecing together the information available, we have no doubt that in camps and places in military occupation at home conditions have not infrequently arisen to which the hygienist would take serious exception, and that occasionally men have had to put up with overcrowding, insufficiency of blankets, untenable camping grounds or huts, and other defective arrangements which could have been prevented if medical considerations had been given time and opportunity to make themselves felt, but in the circumstances could hardly have been avoided. If, as we believe to be the case, those responsible for the conduct of the war realise the scope which ought to be given to considerations of hygiene and act on this knowledge, sanitary defects in the great new military organisation which has so rapidly come into being are bound to be remedied as time goes on, and provision for the housing and well-being of the troops, for ablution, excrement disposal, and similar matters will be improved where improvement is called for. It may be added that the Medical Research Committee established under the National Health Insurance Act[5] has undertaken to collect statistical data of sickness and mortality in our armies; no sickness rates in the home forces have been published, but they are generally understood to be satisfactorily low.

Public Health Administration and Legislation.

During the year active progress has been made, and in many cases has continued during the war, in the normal course of public health administration at home. Local developments have received notice in our columns in reviews of the reports of medical officers of health and otherwise, and reference is here made only to a few larger movements. The organisation of institutional provision for tuberculosis, including the provision of new sanatoriums and dispensaries, and the use of existing hospitals for tuberculosis, has proceeded steadily, and its magnitude will be gathered from reports of the Local Government Boards and the Insurance Commissions. The Mental Deficiency Act, 1913, came into operation during the year. Ophthalmia neonatorum was made a disease compulsorily notifiable by an Order of the Local Government Board which took effect in April. For note of some developments in the work of factory inspection and hygiene of occupation which deserve to be recalled, we may refer to the review of the last annual report of the Chief Inspector of Factories in our issue of July 25th. Reports of Departmental Committees on the manufacture of celluloid, petroleum, and flax, in their relation to the health and safety of the workers, have appeared during the year.

The Elementary Education (Provision of Meals) Act, 1914, altered the law of 1906 by legalising the provision of meals by education authorities during holidays and by removing the limitation of expenditure on meals to a halfpenny rate, half the expenditure being now repayable through Government grants. Other grants have been authorised by the Education Department in respect of schools for mothers and similar objects. The question of child welfare and the prevention of infant mortality has also been brought prominently before sanitary authorities by the Local Government Board, and generally much has been done by central and local public authorities both to create and to meet a demand for State-aided "maternity centres" and organisations for the supervision of the health of the child from birth to school age.[6] These and other activities of Parliament and of Government departments have drawn attention to the strain which they impose on our system of local public health administration, and questions of reorganisation of the Public Health Service, including security of tenure and position for local medical officers, have been freely discussed during the year.[7] The Budget of 1914, as originally introduced, promised many things in the interests of public health and proposed to effect considerable changes by greatly expanding the system of Government grants to local authorities. Some of these grants were to be in aid of expenditure on general public health work and dependent on efficiency, while others were earmarked in aid of housing, nursing, maternity and child welfare work, pathological laboratories, and sanatorium provision. Most of these proposals, however, are at present in abeyance.

Other legislation during the year included a short amending Housing Act, and new Milk and Dairies Acts for England and Scotland.[8] The latter measures, taken with departmental orders of the Board of Agriculture in relation to bovine tuberculosis, should do much to improve the milk-supply of the country when they can be put into operation, and their enactment is a matter for satisfaction in view of the fate of previous Bills on the same subject. The issue in August of the valuable report of the Select Committee on Patent Medicines[9] deserves special reference. Summaries of the proceedings of the Royal Commission on Venereal Diseases during the year have appeared in our columns. The report of the committee appointed by the National Insurance Commission to consider sickness benefit claims, issued during the present month, deals with several large questions which may affect the future of public health work in this country, while reference may also be made to the extensive first programme of investigatory work which has now been formulated by the Medical Research Committee.[10]

ANÆSTHETICS.

The International Medical Congress of 1913 has given an impetus to the wider adoption of the newer methods of anæsthetisation, especially in the case of ether. H. Kümmel[1] was one of the earlier adherents of the intravenous etherisation method. His work shows that much of the ether which enters is at once excreted by the lungs. The examination of blood taken from the arm farthest from the site of entry proves that the erythrocytes are unharmed; indeed, necropsies of patients dying soon after the operation emphasised this fact, and have indicated the absence of consecutive damage to viscera. There is no doubt of the value of this method, especially for operations about the head and upper air passages, provided that the precaution is taken to have an apparatus which allows of accurate dosage, an end easily achieved if two supply bottles are in use, the one for saline, the other for ether-saline solution. A Y connexion yokes them together, so that one or the other is constantly flowing. Abroad, as Kümmel points out, isopral is used as a preliminary, especially for sthenic and excitable subjects. Hedonal has been less used of late, being more dangerous than isopral; its employment for children, however, has been chronicled in The Lancet.[2]

The comparison between the actions of chloroform and ether has been admirably worked out by Dr. H. P. FAIRLIE,[3] who adduces some interesting and important conclusions as regards blood pressure. His paper continues previous work to which we have referred. Chloroform depresses blood pressure, and when surgical shock develops the fall is the sum of these depressions. Provided the declension is limited within the safety zone the pressure rapidly rises after the operation. With ether, unless the inhalation is prolonged, a little fall occurs, but if the trauma causes depression of the blood pressure the fall that ensues is as severe as that summing the chloroform and shock total, while the recovery period is prolonged and not devoid of danger. The warning to use chloroform for cases involving great shock is salutary at this time when ether is so widely used and little care is taken to inquire whether or not chloroform should be employed rather than "open ether." FAIRLIE'S experiments show conclusively that the plan of inducing anæsthesia by an ether sequence and maintaining it with chloroform results in the least shock. Intratracheal methods have become more widely used, and many papers dealing with this important matter have appeared. However, misapprehensions appear to exist, and some workers have failed to master the physiological facts enunciated by MELTZER and AUER, the pioneer workers, facts which underlie the safety of the method. We have animadverted upon this in referring to the suggested use of chloroform by intratracheal insufflation.[4] Mr. W. D. MART'S plan is equivalent to giving chloroform by an intubation or tracheotomy tube, and has not the safeguard of the true intratracheal system, in which pulmonary plus-pressure protects the lungs from the entry of blood from the mouth by establishing a powerful expiratory current of air. Dr. M. S. PEMBREY[5] found that during intratracheal insufflation the average rate of pulmonary ventilation is 16 litres per minute, the extremes being 8 litres and 30 litres; the latter induced apnœa, which is undesirable. Dr. G. MARSHALL having examined blood pressure during the use of this method noted but slight change; 5 to 10 mm. Hg below the mean pressure resulted in prolonged operations.[6] He remarked that the blood pressure varies directly with the CO_2 tension. The use of the oil-ether-rectal method of GWATHMEY[7] has been discussed not wholly favourably.[8] Dr. LUKE found among his patients in the St. Luke's Hospital, New York City, that intestinal cramp, painful abdominal fulness, persistent anal irritation, and unduly prolonged induction were common complications. More serious sequelæ were dangerous respiratory depression, "over-dosage," colitis, proctitis, and an alarmingly prolonged period of torpor.

P. KLEINSCHMIDT[9] gives his clinical experience of rectal anæsthesia by the use of isopral. In 43 cases he used 0·1 grm. (per kilo body weight) per rectum. Although some successes occurred, his verdict is that the method is unreliable as excitement, even maniacal, and toxic effects were evoked. We note that Dr. CRILE'S[10] "kinetic theory of shock, and operation without shock" has found many adherents, perhaps rather to his methods than to his theory, and English workers express satisfaction with their results. Another system to which many papers refer is the Roth-Dräger ether-chloroform-oxygen method, a truly dosimetric plan, and one which is gaining popularity on the continent. H. HINTERSTOISSER[11] as well as Dr. BRAUER notice the danger of giving narcophin, morphine, and like drugs to patients after the operation in cases in which the morphine-scopolamine-ether or chloroform sequence has been adopted. The respiratory centre becomes blunted and undue CO_2 tension is apt to follow. The important subjects of status lymphaticus and post-operative toxæmia (delayed anæsthetic poisoning) have received attention in several valuable communications.[12] Dr. G. GELLTHORN,[13] dealing with spinal analgesia in gynæcological operations, remarks upon the unrecognised frequency of acetonuria in this connexion.

The foundation of a Society of Anæsthetists in Scotland mentioned in THE LANCET[14] is a sign of progress. Dr. W. H. HORNIBROOK[15] makes a vigorous protest against the relegation of expert anæsthetists to a subsidiary status, while Dr. A. C. VANDIVER[16] discusses the germane subject of the legal status of trained nurses who give anæsthetics. The following useful papers may be consulted with advantage: Analgesia, H. NEUHOF,[17] L. KENDIRKJY,[18] M. TRANGOTT,[19] DOLLINGER,[20] HONIGMANN,[21] and A. H. MILLER.[22] Dr. W. A. SCHTANGE'S[23] paper is at once most valuable and novel. He elaborates his "heart test" as to whether an inhalational anæsthetic may be safely given. It depends upon the patient's ability to hold his breath without cardiac effect up to or beyond the normal, which he places between 30 and 40 seconds.

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

THE ROYAL NAVAL MEDICAL SERVICE.

Towards the end of 1913 the Lords Commissioners of the Admiralty adopted certain recommendations of the Medical Consultative Board, made with the object of remedying the alarming shortage in the medical department. Disciplinary control, as regards minor punishments, of the sick berth staff at Haslar, Plymouth, and Chatham, was delegated to the senior medical officers at these stations. The senior medical officer is now to preside at medical surveys; the director-general has control over the publication of papers on professional subjects; private practice is allowed; the publication of a journal is approved of; and the charge of the large naval hospitals at Malta, Gibraltar, Bermuda, and Hong-Kong is now in the hands of the senior medical officer. These are substantial concessions to justice and common sense. There are other grievances, such as the old-standing one of cabin accommodation, that have still not been dealt with satisfactorily, and the creation of specialist appointments, as in the Army Medical Service, is now long overdue, the experience of the army having for many years demonstrated its value and true economy.

The obituary list includes the name of Surgeon-General MAXWELL CRAIG, C.B., who was first principal medical officer of the hospital ship *Maine* during the Boer War. The naval director-general, Surgeon-General A. W. MAY, was advanced to the rank of K.C.B. on the King's birthday.

THE ARMY MEDICAL SERVICE.

The scientific research work, of which results have been published during the past year, includes a continuation of the experimental investigations of the Sleeping Sickness Commission by Sir DAVID and Lady BRUCE, Major D. HARVEY, Major A. E. HAMERTON, and Captain D. P. WATSON; and of the work of Lieutenant-Colonel T. W. GIBBARD and Major L. W. HARRISON on treatment of syphilis with salvarsan. Lieutenant-Colonel W. W. O. BEVERIDGE, D.S.O., conducted an inquiry into the keeping properties of condensed milk at the temperatures of tropical climates. An interesting practical test as to the sufficiency of the existing field service ration was carried out by Colonel C. H. MELVILLE, Major W. W. BEVERIDGE, and Captain N. D. WALKER, assisted by Professor J. S. HALDANE and Dr. M. S. PEMBREY. The conclusion arrived at was that the ration should be increased, particularly in the constituents of fatty and saccharine material, so as to bring it up to 4600 Calories.

Personnel.

The most important changes in personnel during the year have been the appointment of Sir A. SLOGGETT to be director-general consequent on the retirement of Sir L. GUBBINS. Surgeon-General W. G. MACPHERSON became deputy director-general in succession to Surgeon-General W. BABTIE, V.C., who became director of medical services in India. Major S. L. CUMMINS was appointed professor of pathology at the Royal Army Medical College, in succession to Sir W. LEISHMAN, F.R.S., who is now expert in tropical diseases on the Advisory Board. Consequent on the war very numerous changes have taken place. The office of director-general is for the time duplicated; Sir A. SLOGGETT is now director-general of the Expeditionary Force across the Channel, and Sir A. KEOGH is in charge of the office at home. During the autumn Sir A. KEOGH spent a considerable time on the continent as Chief Commissioner of the British Red Cross Society, and is consequently fully acquainted with the military medical conditions and requirements. Surgeon-General S. HICKSON has succeeded Surgeon-General M. W. O'KEEFE as inspector of medical services.

A new committee has been appointed to advise the Secretary of State on sanitary matters, which is really the resuscitation of a former one that did good work in its day and was improved out of existence without due consideration. The chairman is Brigadier-General F. J. ANDERSON, R.E., and the members include Sir F. TREVES, Dr. A. NEWSHOLME, Dr. H. R. KENWOOD, Dr. JOHN ROBERTSON (Birmingham), Colonel W. H. HORROCKS, and Major C. E. P. FOWLER.

Obituary.

Sir ANTHONY HOME, V.C., K.C.B., was the most distinguished army medical officer of his time. He had served through the Crimean and Mutiny campaigns, winning his V.C. at Lucknow, and was subsequently on active service in China, New Zealand, and Ashanti. His autobiography, "Service Memories," edited by Colonel C. H. MELVILLE, is a striking record of successful, indeed brilliant, work in many spheres of action. In spite of the numerous perils he had encountered he lived to be 87. Sir JOHN BY COLE READE served through the Crimea, the Mutiny, and the Second Afghan War, and lived to be 82. Lieutenant-Colonel CHARLES DALTON had received both the British and French Humane Societies' medals for jumping overboard off the coast of South America, when the *Cotopaxi* went down. In West Africa he also performed notably gallant actions, also in the South African War.

THE INDIAN MEDICAL SERVICE.

Scientific Research Work.

Work continues steadily at the various bacteriological institutes in different parts of India, but nothing of outstanding importance in discovery has occurred during the past year. Researches have been conducted in relation to antimalarial measures in the Meerut district and elsewhere, and distinct advance seems to have been made in some directions. An eighth Plague Report has been issued, dealing chiefly with the mechanism of transmission and the bionomics of rat fleas. A third All-India Sanitary Congress was held at Lucknow in January, at which 21 resolutions were carried, relating to all branches of sanitation. The papers read and discussions added largely to the general fund of knowledge in various directions, and it may be hoped that progress will be made in at any rate some of these directions. At Calcutta a school of tropical medicine has been established which may be expected to prove its usefulness in a very short time. Proposals have also been made for the establishment of a similar institution for the Bombay Presidency at Parel; the existing laboratories at the old Government House have been improved and renovated, but no funds have yet been allotted to enable the institution to be carried on in a manner commensurate with its importance to the State.

During the year the Indian Government issued a weighty resolution, laying down the broad principles on which sanitary advance in India must be based: (1) knowledge of the people, their customs, &c., and success in securing their coöperation; (2) recognition of the diversity of conditions in a country which contains many different races, creeds, and communities, and exhibits almost every variety of climate; and (3) need for preliminary local inquiries.

Organisation.

An order was issued in April, 1914, that medical officers and subordinates in military employ should render medical assistance gratuitously, when called upon to do so, to civil departments; and *vice versâ* civil medical officers and subordinates should give similar assistance to military departments. This is an extension of an old order of 1881, but the order has been drafted in such a slovenly manner that friction is certain to arise unless it is more precisely worded. It should be definitely stated who are entitled to call upon the medical officer for his services, and under what circumstances.

An inquiry was held by the Public Services Commission in India as to the conditions and prospects of the medical department at the end of 1913, and the director-general and other officers gave evidence. The question of rewards for original research has been discussed by Sir RONALD ROSS, Professor W. J.

SIMPSON, and others. The official mind seems to be unable to perceive that ROSS'S work was of any substantial benefit to the State or the community, or deserving of pecuniary recognition. Nothing could be better calculated to repel the zealous student, with inclinations towards scientific research, from entering the medical service of the Indian Government, than a study of this correspondence. Dissatisfaction has been publicly expressed in Burma at the inadequate provision of European medical officers in the province; the Chamber of Commerce considers that the policy of repression of the Indian Medical Service is detrimental to the progress of the country. The local government replied sympathetically, stating that the need for more European civil surgeons had been represented to the Government of India.

The education and qualifications of military assistant surgeons in India have been under the consideration of the Examinations Committee of the General Medical Council, whose report, presented by Sir CHARLES BALL, has been transmitted to the India Office.

Personnel.

On the occasion of the KING'S birthday the honour of knighthood was conferred on Lieutenant-Colonel LEONARD ROGERS. Colonel C. C. MANIFOLD and Lieutenant-Colonel W. R. EDWARDS received the C.B., and Lieutenant-Colonel G. J. HAMILTON BELL, Lieutenant-Colonel W. MOLESWORTH, and Lieutenant-Colonel E. D. W. GREIG received the C.I.E. Colonel W. B. BANNERMANN has been appointed Honorary Physician to the King, and Colonel R. W. S. LYONS has become Surgeon-General with the Government of Bombay. Sir PARDEY LUKIS has had his tenure of the office of Director-General, Indian Medical Service, extended for two years, until Dec. 31st, 1916.

The obituary list includes the names of Sir ARTHUR BRANFOOT, K.C.I.E., lately President of the India Office Medical Board, and formerly surgeon-general with the Government of Madras; Sir TREVOR LAWRENCE, formerly of the Bengal Medical Department, who served through the Mutiny; and Sir ANNESLEY DE RENZY, K.C.B., who served in the Burma War of 1852, was present at the capture of Lucknow, was First Sanitary Commissioner of the Punjab, and was principal medical officer of the Naga Expedition in 1879. Surgeon-Major A. C. MACLEOD took his M.R.C.S. in 1840 and entered the Madras Service in 1846. He served in the Mutiny campaign and had long been the senior officer on the Madras Retired List.

FORENSIC MEDICINE.

The legislative season of 1914 produced nothing of great medical significance, nothing, that is to say, upon the scale of the National Insurance or Mental Deficiency Acts, nor can it be said that the law courts have witnessed the trial of any case of outstanding medical importance. Nevertheless, to borrow the phraseology of the official *communiqué*, the science of medicine at several points has consolidated its position, repulsed attacks, and made appreciable progress. More particularly is this the case where the activities of the quack have brought him into contact with the law. The importance of successes in dealing with persons of this class under the law as it stands lies in the fact that the medical profession not unreasonably looks forward to seeing the law eventually strengthened. In a democratic country the existing state of affairs is not likely to be amended in a direction disapproved by the electorate, and verdicts gained against fraudulent impostors afford some indication that the public, represented in a particular instance by a judge and jury, is ready to look upon quacks and quackery as public dangers of a preventable character.

We may refer more particularly to the trial of MILLER at the Old Bailey,[1] when Mr. Justice ROWLATT, in passing sentence after a verdict of manslaughter, said that the conviction was of importance as showing that persons who with no, or little, knowledge dealt with dangerous poisons could be found guilty of a crime in spite of "tall talk about cures, wonderful mental treatment, the unity of the infinite, and all that sort of stuff." His lordship also intimated that on future occasions of a similar character he might not be so lenient. No less satisfactory was the conviction at the same court earlier in the year of DELVINE,[2] whose exploits as a "cancer expert" caused him to be "wanted" in many places besides London, where he received a sentence of 15 months' hard labour. Another cancer expert[3] received a warning from the coroner at Altrincham after an inquest upon one of his patients which will doubtless inculcate caution on his fraternity. Cases in the civil courts, also tending to discredit and disconcert the unqualified person who pretends to treat his neighbours in illness, may be noted. In two of these the Society of Apothecaries recovered the full penalty of £20 against defendants (BURDEN[4] and PURDUE[5]) whose patients became the subjects for coroners' inquests. The fact that these actions can be successfully brought, and the full penalty recovered, is an indication that the courts and the legislature do not regard the principle of protecting the public as obsolete, and would be willing to see its application extended. The success of plaintiffs in civil actions where they have been injured by sham practitioners, particularly in dental cases,[6] has occurred in 1914 as in other years, but the victims are generally unwilling to admit themselves duped or shrink from the expense and annoyance of litigation. Impostors who pose as medical men and even give medical certificates generally end in the clutches of the criminal law, and two of these sentenced in the past year may be referred to. One of them,[7] who used the names of a medical man practising in Africa, was sentenced to a month's imprisonment, after having apparently imposed on the public for some years. The other, J. CUBBIN, pleaded guilty at the December Sessions at the Old Bailey to giving medical certificates without being qualified, and was sentenced to three years' penal servitude, being already a convict on licence.

Other happenings in forensic medicine during the past year suggest a growing general recognition of the dangers of quackery. The Report of the Select Committee on Patent Medicines[8] is not a document which Parliament is likely to disregard when there is time once more for domestic legislation. Cases of a different character from those referred to above which deserve mention include the judgment of the Court of Appeal in EASTES *v.* RUSS,[9] involving the consideration of important points with regard to covenants in restraint of trade, their interpretation, and their reasonableness; and the case of Hughes *v.* Robertson,[10] in which Lord Anderson in the Court of Session, Scotland, usefully summed up the points to be considered by medical men when asked to hold post-mortem examinations, where the authority of the person making the request may not be quite clear.

[9] Delivered in 1913, but see THE LANCET, Jan. 3rd, 1914, p. 55.

In conclusion, we may congratulate those medical men who by legal action have successfully defended their professional characters against aspersion. Among these special reference should be made to Dr. A. Drury,[11] who brought an action against the officers of the National Antivaccination League, securing a settlement upon terms favourable to himself, and Mr. W. J. C. Keats,[12] accused of cruelly flogging boys in the Camberwell Infirmary. Dr. Warrington Yorke[13] should be included with these in that before magistrates and upon appeal to the High Court he successfully repelled unwarrantable charges of cruelty made upon him in connexion with his work as director of the Runcorn Research Laboratories at Crofton Lodge.

It may be safely concluded that in the eventful year 1914, so far as the records of the law supply evidence, the medical profession has strengthened and consolidated its position in the public esteem.

DENTAL SURGERY.

During the past year considerable attention has been drawn to the importance of oral sepsis. In the July and August issues of The Lancet we published several letters on oral sepsis and the extraction of teeth. The discussion was introduced by Sir James F. Goodhart, who uttered a warning against the free extraction of teeth for the removal of sepsis. The writers who condemned this proceeding and considered that the consequences of oral sepsis were exaggerated were ably answered by those who think that its importance is even yet not sufficiently recognised. A good deal of the misconception in the minds of many with regard to this subject is probably due to a lack of appreciation of the modern concepts of general pathology and the special pathology of the disease. It is more than probable that the slow but constant absorption of the organisms from the affected area does the damage, and this may be taking place in what is to the untrained eye an apparently clean mouth. The question to be answered by the opponents of free extraction is this: Can they guarantee to rid the individual of that source of infection without resorting to efficient drainage—namely, extraction? The recognition of the importance of this radical treatment has been emphasised by Mr. W. M. Beaumont in a paper on the Evolution of Iritis,[1] and by Mr. Wilfred Trotter,[2] in his article on Prognosis in Cancer of the Tongue.

It is satisfactory to be able to record that scientific methods are being more widely adopted in attacking the problems of dental pathology, an excellent example being the work carried out by Dr. W. J. Gies[3] on the relation of potassium sulphocyanate to dental caries. His work satisfactorily shows that this salt, in the proportion found in normal saliva, does not in any way influence caries of the teeth. The papers published on abnormalities in position of the teeth show that an earnest endeavour is being made to ascertain the real cause of these conditions. A study of the animal kingdom has shown that many of the irregularities of the teeth seen in man are met with in animals, and that the question of the relative variation of the teeth and jaws is in some measure associated with the production of a crowded arrangement of the teeth.

ANATOMY.

The year 1914 is not one to be looked back upon as having witnessed any very marked progress in the study of anatomy. Much detailed work has been done both here and in America, and the number of well-studied human embryos of which we have accurate and permanent reconstructions has greatly increased. Perhaps most finality has been reached by the publication of what is a summary of many investigations upon the origin and nature of the lymphatic system by Professor George S. Huntington, of Columbia University.[1] On the whole it may be said fairly that the original work published during the year may be regarded as bricks and mortar—in many cases very good building material indeed—but that very little actual building has been attempted. From the continent no anatomical literature has been received since the outbreak of war.

Both here and in Australia the discussion on the now famous Piltdown fragments has been continued, and much good has resulted, for everyone who ventured an opinion upon the subject weighed with the greatest care the reliance he could confidently place on any methods he employed; and in this way we have obtained some certain knowledge of the efficiency, and the limitations, of anthropological methods. The recent bringing to light of the Australian skull will certainly add a new phase to the progress of research into the early history of man.

Death has taken heavy toll of anatomists in 1914. In Walter Holbrook Gaskell is lost the thinker and worker who, perhaps more than any other man of recent times, shook zoological beliefs to their foundations and set men thinking. It should be a source of some satisfaction to anatomists to remember that it was their journal which opened its columns to the revolutionary work of Gaskell at a time when the proper publication of his ideas was by no means easy. Charles Barrett Lockwood, whose ten years' work in the anatomy rooms of St. Bartholomew's Hospital laid the foundation of a wonderfully sound anatomical knowledge, was one of the founders of the Anatomical Society. Lockwood, in his "suspensory ligament," had attained a distinction given to no other living anatomist in that his name was indelibly associated with a structure of the human body in the nomenclature of the British schools. William Bruce Clarke also taught anatomy to successive generations of students at St. Bartholomew's, where his career as demonstrator opened in 1882. For six years he taught in the rooms, afterwards being lecturer on anatomy at the same school. The death of Richard John Anderson of Galway deprives anatomy of a personality that can ill be spared. In 1846 John Goodsir was lamenting the rarity of the anatomist who could be said to have a knowledge wide enough to embrace all that was contained within the ken of such men as Haller, Hunter and the Meckels.

Since Goodsir's day that type of man has become still more rare; and without going so far as to say that in ANDERSON we have lost such a one as these, we may safely affirm that for wide, varied, and curious information upon zoology, morphology, and the other kindred subjects he knew no equal.

CHEMISTRY.

Whilst it would be untrue to say in the now familiar words of the *communiqué* "there is nothing to report" in regard to the chemical progress of the past year, there has been no development of a sensational character. During the past few months the importance of applied chemical science has been realised by the nation, and organisations have been begun which promise to found industries which have been either lost or neglected for reasons which reflect little credit either to science or to industry. In many directions there can be no question that British industries are handicapped by the difficulty of obtaining raw materials, but it is equally true that for far too long a time this country has exported vast quantities of valuable raw materials out of which fine products, as. for example, dyestuffs, synthetic remedies, could have been made here as satisfactorily as anywhere else. Amongst the many morals to which this great war will surely point will be our duty to establish an independence in this country in regard to the supply of many valuable manufactured articles, and to give every conceivable encouragement to scientific training and its application to industrial operations.

Synthetic Studies.

Early in the year it was announced that the synthesis of certain organic compounds had been affected by photo-energy. Sugars, it was confieently asserted, could be built up from carbonic dcid gas and water by exposing these simple compounds to the action of ultra-violet light. We are not aware that these statements have been confirmed, but they open a fascinating field for study if only they suggest following the lead of sunlight which actuates the great synthetic processes in plant life.

Radium.

The hope has been expressed that the activities of radium might be obtained perhaps by electrical means and render us independent of the supplies of this ultra-rare material. However this may be, Sir WILLIAM RAMSAY has suggested in our columns an economical and effective way of employing radium in therapeutic practice. He recommends its application in the form of niton or emanation rather than as a salt of radium on the ground that in the latter case there is considerable risk of loss of the precious metal, while this method does not ensure a continuous application, as, for example, through the night. The production of niton from radium is continuous, it goes on night and day, and the radiating power of niton is 75 per cent. of that of the radium from which it is derived. It seems to be accepted that the favourable results of radium treatment are due to its stimulating effects upon cell activity and generally in promoting healthy metabolism.

Metallic Colloids as Germicides.

The search for a germicide which will kill disease organisms, whilst producing no toxic action on the human organism, is meeting with some success in the series of metallic colloids which have been prepared. It is not at all improbable that as this study is pursued colloidal preparations may be found which will supersede the complex arsenical compounds used in syphilitic disease. Colloid preparations of mercury, arsenic, and silver have at any rate been prepared which, while effective in quite small doses in killing bacteria and ferments, have no toxic action on the body.

It is suggested that the action is due to the fact that each metallic colloidal particle carries a charge of electricity, and that these particles are all electrified in the same manner and therefore are mutually repelled, so that, in spite of their very active movement, they do not and cannot touch each other, and thus do not lose their charge. When, however, a foreign neutral body (such as a disease organism) enters the solution these electrical particles are not repelled from it automatically, but may even be attracted to it if it happens to carry a charge of the opposite polarity by the action of adsorption. The organism in any case, being of much greater mass, will receive the charges of many thousands or millions of particles of metal, and this may conceivably account for its death. The metallic colloids, as their preparation is improved, may thus come to be of distinct service in medical and surgical practice.

Vitamines.

We are beginning to learn more about vitamines in their relationship to the so-called deficiency diseases, but it must be said that the exact chemistry of these bodies is by no means cleared up. They have recently been suggested as factors in pathogenic processes, as, for example, that of cancer, in which a pathological new growth of tissue appears, owing possibly to the stimulus of a special vitamine. The question as to whether it is possible to inhibit this new growth by careful regulation of the diet with the view of excluding the vitamine has seriously been raised. We must clearly await more definite evidence before such a line of argument can be pursued with advantage.

CONTRIBUTIONS FROM "THE LANCET" LABORATORY.

Special investigations have involved a very decided increase in the number of analytical determinations made this year in THE LANCET Laboratory. The total from all sources last year was 432 and this year it is 835. This increase has been due to (1) a special article on Toilet Soaps from an Economic and Hygienic Point of View, involving 291 analyses; (2) five special articles on THE LANCET Hygienic Test for Gas Fires, involving 305 tests; and (3) 60 analytical estimations in connexion with the work of the Committee for the Investigation of Atmospheric Pollution, the analysis of the collected rainfall at the Meteorological Office, London, being undertaken in THE LANCET Laboratory.

In the column, "Reports and Analytical Records from THE LANCET Laboratory," 67 articles were reported upon, involving 179 analytical determinations.

The test originated in THE LANCET Laboratory early in the year, by which a simple chemical means was found for detecting whether a gas fire permitted the escape of combustion products into the air of the room, has received the endorsement of the gas fire industry, and, as a rule, no gas fire is accepted "unless it has passed

THE LANCET test." We have been appealed to by practically all the leading gas fire makers in the country to submit their fires to this test. This we have been quite willing to do, and the results have been reported in our columns during the year. The standard has been established and is effecting a satisfactory hygienic reform which is calculated to place this system of domestic heating on a higher level than before, and to rid it from the reproach of producing an unhealthy atmosphere.

In THE LANCET of July 18th we published the results of the examination of a golf ball which had been dissected by a person curious to know its composition. When he reached the core there was a sudden ejection of a liquid substance which struck his eye with some violence. A serious but happily temporary injury was done to the tissue of the eye. Our analysis showed that the fluid under pressure consisted of strong alkaline potash soap.

A feature of the work of THE LANCET Laboratory during the past few months has been the examination of a number of samples which were claimed to replace effectively well-known German preparations.

PHARMACY.

The practice of pharmacy during the past year has been subject to no fundamental alterations other than the changes of the last few months resulting from the state of war.

The National Insurance Acts and other Matters.

Attention has largely been concentrated on a number of considerations arising out of the administrative developments of the Insurance Acts. The most material of these has been the increased demand on the drug fund in many areas and the consequent endeavour to devise ways and means of avoiding deficiencies in the sums allotted for the payment of drugs and dispensing. Various committees set up by the new medical benefit regulations have been occupied with this question but apparently with no completely satisfactory solution. The necessity of utilising to the full their powers of setting in motion the machinery for the surcharging of panel practitioners who prescribe too generously has been impressed upon pharmacists by the Commissioners, and in many areas the systematic examination of prescriptions is being carried out. But, in any case, a heavy discounting of chemists' accounts in many areas appears to be inevitable. Late in the year much adverse comment has been aroused by the action of the Commissioners in requiring Insurance Committees to insert in their agreements with chemists a clause providing for reduced fees for the dispensing of stock mixtures. The operation of the Insurance Acts has required some further alterations in pharmaceutical organisation. Under the new scheme the local pharmaceutical associations are coterminous with local Insurance Committees, and the associations are federated, the central body being an executive committee on which the Council of the Pharmaceutical Society is well represented. The Council of the Pharmaceutical Society has authorised the establishment of a permanent Parliamentary fund for the purpose of maintaining, and if possible increasing, the direct representation of pharmacy in the House of Commons, and the invitation for subscriptions has met with good response.

In the scientific field an average amount of useful work has been accomplished and the result duly recorded at the annual meeting of the British Pharmaceutical Conference[1] and at evening meetings of the Pharmaceutical Society. In connexion with the preparation of legislative measures to give effect to the provisions of the International Opium Convention,[2] the Under Secretary for Foreign Affairs has been in consultation with representative medical and pharmaceutical authorities with a view of ascertaining what changes in the law as to the distribution of dispensed medicines are expedient; he has been informed by the Council of the British Medical Association that in their view it is desirable and practicable to limit the sale to private persons of medicines containing morphine, cocaine, and certain other narcotic drugs dispensed in accordance with a medical practitioner's prescription.

Pharmacists and the War.

In common with all classes, pharmacists have experienced the effects of the war; the volume of business has been reduced considerably and the prices of a large number of drugs have advanced substantially. But owing to the action of the Government, on the advice of a committee of experts, the advance in prices has not been so great or so general as it might have been in the absence of Government intervention; the prohibition of the export of certain drugs and the passing of legislation empowering the authorities to make inquiries as to stocks and to seize stocks if necessary have combined to prevent depletion of material and to arrest undue fluctuations of prices. The increase in the cost of drugs has had the effect of diminishing the profits of panel chemists, who are under contract to supply medicines on terms regulated by a tariff which was drawn up when values were normal; but to some extent the situation has been ameliorated by the action of the Commissioners in allowing payment on special terms for drugs included in a list known as the War Schedule. Some progress has been made in the attempt to manufacture in this country products which were formerly supplied from Germany, but there are many difficulties to be overcome before it will be possible to establish the synthetic drug and fine chemical industry on a satisfactory basis in this country. Only in a few cases have licences been granted to British firms to work German patents or to use German trade marks. In connexion with the free medical treatment of the necessitous dependents of soldiers and sailors, pharmacists have willingly coöperated with medical men. An endeavour has been made to give special help to pharmaceutical refugees from Belgium, and chemists have also interested themselves in the appeal made by the Belgian Doctors and Pharmacists Relief Fund committee.

The report of the Select Committee on Patent Medicines presented to the House of Commons in the late summer has met with the approval of all those whose desire it is to secure measures for the protection of the public health and the suppression of practices indistinguishable from fraud. The British Pharmacopœia, 1914,[3] has been so recently reviewed in these columns that it is not necessary to make further allusion to it here.

HONOURS TO MEDICAL MEN.

The eventful year now closing has been fairly full of honours for the medical profession, and we are proud that one member of our profession has won the V.C. for a most gallant action, and that others have earned the Companionship of the Distinguished Service Order.

The New Year Honours.

Sir Christopher Nixon, a former President of the Royal College of Physicians of Ireland, and since deceased, was sworn of the Irish Privy Council. Sir T. J. Stafford, Medical Commissioner of the Local Government Board in Ireland, received a baronetcy, and three knights were created, these being Surgeon-General Sir A. T. Sloggett, R.A.M.C., Director-General with the Expeditionary Force, Sir T. B. Nariman, physician to the Parsi Lying-in Hospital, Bombay, and Sir Harry Brookes Allen, professor of pathology and Dean of the Faculty of Medicine in the University of Melbourne. In the Royal Victorian Order Sir Rickman Godlee and Sir William Job Collins received the Knight Commandership. Major James Currie Robertson, I.M.S., Sanitary Commissioner with the Government of India, was appointed C.I.E. Surgeon-General Harold George Hathaway, Deputy Director of Medical Services in India, received a C.B. The Kaisar-i-Hind Gold Medal for Public Service in India was awarded to Dr. William Stokes, Dr. Marcus B. Carleton, and Dr. James Shepherd. Surgeon-General Arthur William May, C.B., Director-General of the Medical Department of the Navy, was appointed Honorary Physician to the King.

The Birthday Honours.

Eight new knights were created—namely, Sir Wilmot P. Herringham, Vice-Chancellor of the University of London; Sir William Milligan; Sir Seymour J. Sharkey; Lieutenant-Colonel Sir Leonard Rogers, C.I.E., professor of pathology at the Medical College, Calcutta; Sir Joseph E. Godfrey, late surgeon-general and chairman of the Local Government Board, British Guiana; Sir Thomas George Roddick, late Dean of the Faculty of Medicine of McGill University; Sir T. P. Anderson Stuart, Dean of the Faculty of Medicine at Sydney University; and Sir Alfred E. Thomson, surgeon to the New Somerset Hospital, Capetown. In the Order of the Bath Surgeon-General Sir Arthur W. May received promotion to K.C.B. Dr. Frank G. Clemow was made a C.M.G. Lieutenant-Colonel W. R. Edwards, C.M.G., I.M.S., and Colonel Courtenay Clarke Manifold, I.M.S., received C.B.'s; and Lieutenant-Colonel W. Molesworth, I.M.S., Lieutenant-Colonel G. J. Hamilton Bell, I.M.S., and Major E. D. Wilson Greig, I.M.S., assistant director of the Central Research Institute, Kasauli, were made C.I.E.'s. Major Charles E. Southon, I.M.S., was awarded the Kaisar-i-Hind Gold Medal, Dr. E. D. Rowland, resident surgeon at the Public Hospital, Georgetown, British Guiana, was appointed to the Imperial Service Order, and Dr. Harold Robert Dacre Spitta was appointed M.V.O.

The Victoria Cross.

In the first list of nine officers and non-commissioned officers to whom the Victoria Cross was granted for conspicuous bravery while serving with the Expeditionary Force appeared the name of Captain Harry Sherwood Ranken, R.A.M.C., who died at Braisne on Sept. 25th from wounds received in action. Captain Ranken was awarded the Victoria Cross "for tending wounded in the trenches under rifle and shrapnel fire at Hautvesnes on Sept. 19th, and on Sept. 20th continuing to attend to wounded after his thigh and leg had been shattered."

The Distinguished Service Order.

Among the officers of His Majesty's army who received Companionships of the Distinguished Service Order, in recognition of their services with the Expeditionary Force, were six members of the Royal Army Medical Corps—namely, Lieutenant Henry Beddingfield, for coolness and daring in repeatedly superintending removal of wounded from the firing line under heavy fire; Major Sidney George Butler, for coolness and courage in continuing all day to collect wounded under severe shell fire; Captain Malcolm Leckie (deceased), for gallant conduct and exceptional devotion to duty in attending to the wounded at Frameries, where he was himself wounded; Captain James Stuart Dunne, who during a German attack on Oct. 31st, near Messines, established a dressing station just behind the trenches, and was the means of saving many lives, he himself going several times into the trenches to attend to wounded men who could not be moved; Captain Sidney John Stewart, who went with a party of stretcher-bearers across ground swept by rifle and shell fire to Langemark village and removed 11 wounded men; and Captain Patrick Sampson, who showed frequent and conspicuous gallantry throughout the campaign, especially on Oct. 21st and 22nd, attending wounded men under very heavy shell fire.

The Legion of Honour.

The President of the French Republic bestowed the decoration of the Legion of Honour on the following officers of the Royal Army Medical Corps for their gallantry during the military operations between August 21st and 30th:—*Croix d'Officier:* Major S. L. Cummins. *Croix de Chevalier:* Captain S. E. Lewis, Captain J. T. McEntire, and Captain H. S. Ranken. The latter, as noted above, also received the posthumous honour of the V.C.

Foreign Orders.

During the year Captain R. J. C. Thompson, R.A.M.C., received the Imperial Ottoman Order of the Medjidieh (Fourth Class), as did also Captain Colin Cassidy, R.A.M.C., and Captain William Edward Marshall, R.A.M.C.

GENERAL MEDICAL COUNCIL.

The General Council of Medical Education and Registration commenced its summer session on May 26th, when Sir Donald MacAlister was heartily congratulated on recovery from his late illness. The session lasted five days, and was a quiet and businesslike one. Various steps forward in securing reciprocity between this country and the colonies and India were taken. Approval of the Midwives (Scotland) Bill was expressed and other matters which occupied the attention of the Council were the inspection of examinations and the proofs of the British Pharmacœpia (1914). A cycle of inspection of the qualifying examinations held by the several licensing bodies was decided upon for 1915, but owing to the war the plans made were afterwards modified. The winter session, the hundredth session of the Council, commenced on Nov. 24th, lasted three days only, and was mainly taken up in the consideration of penal cases.

BRITISH MEDICAL ASSOCIATION.

The eighty-second annual meeting of the British Medical Association was held in the University city of Aberdeen, under the presidency of Sir Alexander Ogston, in the last week of July, on the eve of the war, but before anything happened to mar the proceedings. At the annual Representative meeting, which commenced its proceedings on July 24th, a proposal was accepted, for reference to the Council, to consider what steps were necessary to secure that the British Medical Association should become a federation of medical bodies formed for the purposes of special sections of the profession. The Representative Body at the same time reaffirmed its support of the State registration of nurses, and instructed the Council to confer with the British Dental Association as to the best means of combating the evils of unregistered dentistry. The question of forming a special fund to protect the interests of the profession, and the correlated question of whether the fund should be administered by a trust or a trade union, was discussed and it was decided to follow the former policy. In regard to National Insurance the principle was laid down that public money received for treatment in voluntary institutions should belong to the medical staffs to be disposed of as they decided.

A second trial of the action for libel, brought by Mr. C. H. Stevens against the Association, ended with a verdict for the Association, whose action in denouncing the methods of a remedy-monger met with the approval of all medical men, and has now been endorsed by a jury.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

The fifth annual session of this Congress was held in London at the end of July, when a large number of surgeons from all parts of the world, some of them of international reputation, attended what proved to be a very successful and well-organised meeting. Owing to the obvious approach of war, even when its extent could not be foreseen, many of the foreign members of the Congress hurried back to their respective countries before the termination of the proceedings, and the anxiety of some of our American visitors in regard to the contingencies of their homeward voyage curtailed a great many intended visits. All the large general and special hospitals in the metropolis held special clinics for the benefit of the members of the Congress, and the discussions and friendly interchange of opinions showed that the surgery of this country was well abreast of the times from a general point of view. Lessons in special procedure were, however, received by us, and, it is hoped, were also given.

HOSPITAL FUNDS.

Voluntary contributions to hospital charities have not suffered to the extent which might have been expected; the drain on the charitable public this year in consequence of the war has been nobly met.

Metropolitan Hospital Sunday Fund.

Notwithstanding adverse influences, the income of this fund has been maintained. At the annual meeting of constituents, which was held on Dec. 22nd at the Mansion House, it was announced that this year's collection has resulted, under the presidency and treasurership of Sir T. Vansittart Bowater, in a total of £65,400 16*s.* 9*d.*, an increase of £409 compared with last year. The total receipts are made up of £28,700 from congregations, and £36,700 from legacies, donations, and dividends. The Distribution Committee recommended awards to the general and special hospitals, convalescent homes, dispensaries, and nursing associations, amounting to £59,403.

King Edward's Hospital Fund for London.

At a meeting of the governors and general council of King Edward's Hospital Fund held on Dec. 16th at St. James's Palace, it was announced that £140,000 would be distributed among various hospitals, convalescent homes, and consumption sanatoriums. Through Lord Stamfordham the King expressed the hope that the pressing needs of the voluntary hospitals would not be lost sight of during the present crisis. Up to Dec. 12th £370,856 were received on capital account, and on general account after payment of expenses £133,706. The report of the Distribution Commttee, which was presented by Sir William Church, stated that the governors and general council had this year fixed the sum available for distribution amongst the London hospitals at £133,500, as compared with £151,000 distributed in 1913. The Distribution Committee had nevertheless been able to recommend an increase in the total grants to maintenance—£121,150, as against £115,350 last year.

Hospital Saturday Fund.

From Jan. 13th to Dec. 12th the income of this Fund amounted to £20,170, an increase of £251 as compared with a corresponding period of last year. The accounts for 1914 will not be closed till Jan. 11th, 1915.

THE WAR.

The war has naturally occupied a large amount of our space during the last five months of the year, and a great many articles and paragraphs of medico-military interest have been published. For the convenience of our readers we may briefly mention those communications which attracted most attention at the time, or to which future reference is most likely to be made when the medical history of the war comes to be written.

Gun Deafness and its Prevention, W. Jobson Horne, August 15th. Antityphoid Inoculation in the Army, W. B. Leishman, August 22nd and Sept. 26th; G. Dreyer and E. W. Ainley Walker, August 29th; J. J. Graham Brown and F. M. Caird, Sept. 12th. Sterilisation of Water-supplies, G. Sims Woodhead, Sept. 19th. Open-air Hospitals in War Time, Robert Saundby, Sept. 19th. Improvisation of Apparatus in Fractures in Modern Warfare, J. H. Watson and T. Snowball, Sept. 26th, Oct. 3rd and 10th. Sterilisation of Potable Waters, J. C. Thresh, Sept. 26th. Ambulance Work in France, James Donelan, Oct. 3rd. Transport of the Wounded in War, E. Kondoleon, Oct. 10th. Wounds of the Present Campaign, G. H. Makins, Oct. 10th and 24th. Shell Wounds in Naval Warfare, B. Pick, R. A. Rankine, and J. Lambert, Oct. 24th. Traumatic Tetanus, M. H. Gordon, Oct. 31st. Surgical Lessons of the War, D'Arcy Power, Nov. 7th. Problems of Gunshot Fractures, E. W. Hey Groves, Nov. 14th. Treatment of Wounds in War, W. Watson Cheyne, Nov. 21st. Wounds during the Fighting in Flanders, G. H. Makins, Nov. 21st. Position of Belgian Doctors and Pharmacists, C. Jacobs, Nov. 21st. Bromidrosis, T. H. C. Benians, Dec. 5th. Wounds Produced by the Modern Bullet, G. H. Makins, Dec. 12th. Germicidal Action of Colloidal Silver, W. J. Simpson and R. T. Hewlett, Dec. 12th. Treatment of Wounds in War, Anthony Bowlby, Dec. 19th. Our Army's Teeth, F. NEWLAND-PEDLEY, Dec. 19th.

Discussions at the Medical Society of London on Surgical Experiences of the Present War, and on Treatment of Tetanus were reported in THE LANCET of Nov. 21st and 28th and Dec. 12th.

The outcome of all the communications which we have received, as well as of those which have been published, is decidedly satisfactory as regards the general health of our own troops. The incidence among them of infectious disease has been small, almost infinitely smaller than some of the gloomier forecasts, and the treatment of the wounded has been undertaken in a systematic manner as soon as the military conditions of the campaign made this in the least possible. The work of the Royal Army Medical Corps has been splendid, and the public coöperation generous and, as a rule, remarkably effective. The heroic remnant of the Belgian army has been sorely tried by sickness, as was only to be expected when the conditions under which it has struggled so fearlessly for nearly five months are recalled. Behind the vastly extended lines of our French Allies the number of sick has been in certain districts large, but the grave dangers of widespread infection have been met by strenuous organisation and personal devotion. Sufferings which no words can describe have been endured, and remain for endurance, but from the medical point of view the story is satisfactory and the outlook hopeful.

Annotations.

"Ne quid nimis."

THE ORIGIN AND NATURE OF GRANULAR AND HYALINE RENAL CASTS.

THERE is a well-known disparity of opinion with regard to the origin and composition of renal casts. Rovida and Padoa consider granular casts the products of a secretion of altered epithelial cells in the renal tubes, while Senator and Olivero believe that they originate by a process of transformation of necrosed epithelium. Hyaline casts have been regarded as a product of epithelial secretion or as formed by albumin exuded from the glomeruli and coagulated in the tubules. An experimental note on the subject has just been published in *Il Policlinico* for Nov. 29th by Dr. Cesare Minerbi, who has availed himself of a new method of staining urinary sediments discovered by W. Vecchiati by using Pappenheim's solution. By this process the epithelial cells of the tubules, whether free or as epithelial casts, take a bright sky-blue tint, faintly violet in the protoplasm, reddish purple in the nucleus which is clearly mapped out. Granular casts also are coloured blue with a more or less tendency to violet. They show here and there included epithelial cells from the tubules, with their marked characteristics, although more or less altered, inasmuch as the protoplasm does not change colour, and the nucleus, although undergoing a chromatolysis more or less advanced, is perfectly recognisable. In sediments where there is a large quantity of granular casts it is easy to follow the phases of transformation from epithelial to granular casts. The process seems to be as follows. The cells fuse and agglutinate their protoplasm, the nucleus becomes a prey to chromatolysis, and disintegrates, its fragments being disseminated throughout the protoplasm and gradually dissolved. Such fragments assume under the staining described a colour no longer purplish but tending to yellowish brown. In this manner is produced a granular cast, formed in substance from the protoplasm of the epithelium of the tubules and containing granules which are partly nuclear detritus and partly derived by the "lysis" of the protoplasm. Hyaline casts only in rare instances take a faint pink stain; for the most part they remain absolutely colourless and there is never any evidence of any trace of nuclear débris. Commenting on this fact, Dr. Minerbi is of opinion that hyaline casts are derived from blood casts, the red cells of which lose their hæmoglobin under the influence of the hypotonic solvent action of the urine.

Dr. F. Gowland Hopkins, F.R.S., university reader in chemical physiology, has been elected to the newly constituted professorship of biochemistry in the University of Cambridge.

DONATIONS AND BEQUESTS.—Among a large number of charitable gifts left by the late Miss Julia Crokat are £1000 each to St. Mary's Hospital, the Hospital for Sick Children, Great Ormond-street, and £500 each to the British Home for Incurables and to the Royal Hospital for Incurables.—The Royal Dental Hospital, Leicester-square, has received a donation of £1000 from Mr. Somerset Beaumont.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Dec. 15th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward: Not observing the antiseptic precautions prescribed by Rules E. 3 and 7; persistently neglecting and refusing to give reasonable facilities for the inspection by the local supervising authority of the register of cases, bag of appliances, and place of residence, and an investigation of the mode of practice, as required by Rule E. 24. Neglecting to adopt the antiseptic precautions required by Rules E. 3 and 7, and to take and record the pulse and temperature of the patient, as required by Rule E. 13. Medical aid having been sought, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 21 (1); not being scrupulously clean, as required by Rule E. 1; not cleansing the eyelids of the child in accordance with Rule E. 15, and being unable to take the pulse or temperature of patients, and in consequence being unable to comply with Rule E. 13. That being in attendance as a midwife at a confinement and the child suffering from inflammation of and discharge from the eyes, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5). The midwife attending a confinement not wearing a clean dress of washable material, as required by Rule E. 1, and not taking to the confinement the appliances and antiseptics prescribed by Rule E. 2.—At a meeting of the Board at Caxton House, on Dec. 17th, Sir Francis Champneys being in the chair, a letter was considered from the Secretary of the Association for Promoting the Training and Supply of Midwives transmitting for the information of the Board returns obtained by the association from local supervising authorities as to the difficulty experienced in obtaining the services of a registered medical practitioner when summoned in emergencies on the advice of a midwife. The Board directed that the association be informed that the Board sympathises with it, and has repeatedly urged the necessity of securing the payment of medical practitioners when summoned to cases in charge of midwives, and that the Board will use its endeavours at the proper time to get such a clause passed, and further suggests that the association should use their influence to get an amending Bill passed as soon as possible.

STRETCHERS FOR THE WOUNDED IN THE TRENCHES.

By G. K. Aubrey, L.M.S.S.A. Lond., L.R.C.P. Irel.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS (SPECIAL RESERVE).

The official pattern of stretcher is often useless as a means of transporting the wounded through the trenches, not only because of its breadth, but particularly also of its great length. Here is the official description of the army pattern now in general use, taken from "R.A.M.C. Training":—

> In Mark II. stretchers the canvas, which is tanned, is fastened to the pole by copper nails through an edging of leather; the poles are square and kept apart the required distance by two flat, wrought iron, jointed bars called traverses, and are fitted on the under side with steel U-shaped runners. A pillow and a pair of shoulder-slings are provided with each stretcher. The pillows are wedge-shaped, varying from 1½ to 3½ in. in thickness. There are eyelet holes in the canvas of the stretcher at both ends for the attachment of the pillows by thin leather thongs. The sling, which is of tanned web, has at either end a loop, one of which is furnished with a brass grip-plate, by means of which the sling can be lengthened or shortened; at the opposite end is a narrow, transverse strap fixed at right angles, which is buckled round the stretcher when closed.
>
> The dimensions of Mark II. stretchers are: Length, canvas, 6 ft., pole, 7ft. 9 in.; width, total, 1ft. 11 in.; height, 6 in.; weight, 30 lb.; tonnage for freightage, without pillow 0·0364 ton, pillow only 0·015 ton.

The breadth of Mark II. cannot be lessened because of the iron "traverses" which keep the poles a fixed distance apart, and though it is true that in places the width of trenches is enough to admit of its passage and of the men passing it in the opposite direction, the length of this stretcher is an absolute bar, for a trench twists and turns and doubles constantly upon itself in U-shaped curves, along which it simply cannot be taken. Consequently, removals from the trenches to the Regimental Aid Post have to be effected at night under cover of darkness, the bearers lifting the man out of the trenches altogether, and at considerable risk to him and to themselves conveying him across open country and taking chances that none of the stray bullets and ricochets which are flying about at all hours will find a billet in any member of the party.

If the soldier is hit in the morning and cannot walk he is compelled to wait till night, lying long hours in a "dug-out" or some corner out of the way; and it must be obvious that a great many cases would be much better off if they could be got down without delay, through and under cover of the trenches.

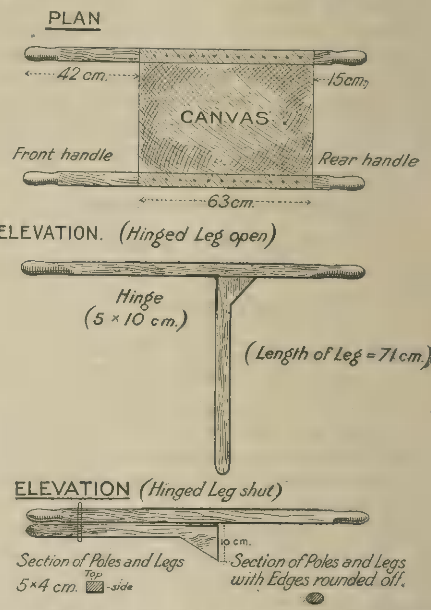
This is the *raison d'être* of the short Fusilier trench stretcher, which is described and figured below. The one which I made, with the skilful assistance of Bandsman W. H. Ayres, Royal Fusiliers, has proved of much service from the start, and several have since been made by the Royal Engineers and are now in use in the brigade.

The total length of this stretcher from end to end of pole is only 120 cm. (4 ft.), its width 52 cm. (20½ in.). In front of the canvas, which is 63 cm. long by 52 cm. wide (25 in. by 20½ in.), the poles extend 42 cm. (16½ in.), while in rear they merely form handles 15 cm. (6 in.) long. To the under surface of the poles—which are 5 cm. (2 in.) wide by 4 cm. (1½ in.) thick—a leg of the same dimensions and 71 cm. (28 in.) long is attached by a hinge the width of the pole and leg, and 10 cm. (4 in.) in length, at such a distance from the front end of the pole that when the leg is folded forwards underneath the latter the ends of the leg and of the pole shall be flush. (The dimensions in inches are approximate.)

The comparative dimensions of Mark II. and the trench stretcher are accordingly as follows:—

	Mark II.	Trench.
Length of pole	7 ft. 9 in.	4 ft. 0 in.
,, canvas ...	6 ft. 0 in.	2 ft. 1 in.
Width, total...	1 ft. 11 in.	1 ft. 8½ in.
Height	0 ft. 6 in.	0 ft. 4 in. (with leg folded; 2ft. 8½ in. with leg down).

The shoulder slings of Mark II. stretcher are used with the trench stretcher, and its pillow, as a cushion, is placed longwise on the canvas between the poles. The patient is seated on the canvas, his head and back resting against the breast of the rear bearer, whilst his feet hang just clear of the front bearer's legs. The strap shown as tying the folded-up hinged leg to the pole can be used to sling loosely and give support to one or other of the patient's legs without appreciable inconvenience either to him or the front bearer. If necessary, a bandage or strap may be passed in front of the patient's chest and attached on either side to the shoulder sling which goes from the rear bearer's shoulders to the handles. When carrying a man the hinged legs hang from the poles, and are so placed as to take the weight of the patient evenly if the bearers lower the stretcher a little to rest or change, and very little effort is needed to hold the contrivance steadily balanced.



Diagrammatic sketch of Captain Aubrey's "Fusilier" trench stretcher. Total length, 120 cm.; total width, 52 cm.; canvas seat measurement, 63 × 52 cm.

In conclusion, the stretcher I have devised and described does not profess to replace or to be in any way an improvement on the army pattern, Mark II., where such can be used, or to be a perfect specimen of its particular kind. I have no doubt that it can be greatly improved, and sincerely hope that suggestions to enhance its value will be made by some of those who read this article.

A FATAL CASE OF POISONING BY TETRACHLORIDE OF ETHANE.

ON Saturday last, Dec. 19th, Mr. Luxmore Drew and a jury resumed an inquiry into the cause of death of an employee at an aeroplane factory, when highly interesting scientific evidence was given in accordance with which the verdict was returned. The deceased died in the wards of the hospital where he had been taken after becoming ill at the factory, and evidence was given by the Aircraft Manufacturing Company, the proprietors of the factory, describing the procedure of applying "dope," this being the work which was presumed to have led to the condition. From the evidence it was obvious that there had been a considerable number of cases of sickness, in some of which jaundice was present, while it was also evident that the "doping" was attended with considerable smell. A member of the firm which manufactured the "dope" said that the factory contained draught fans to remove the fumes and gave other evidence of proper care for the operatives. They were, he said, on the look out for a new factory, otherwise the installation of fans would have been made several months previously. Mr. John Chapman, the sanitary inspector of Hendon, and Mr. F. W. Andrew, the medical officer of health of Hendon, both gave evidence, which, as far as it went, showed that sanitary precautions had been taken in the factory.

Evidence as to the Nature and Effects of Dope.

Dr. William Henry Willcox deposed that he was one of the physicians of St. Mary's Hospital and official analyst to the Home Office. He had prepared a report on this case of Gilbert Moody, deceased. On Nov. 5th last he carefully examined Moody at the out-patient department of the hospital, and found him suffering from jaundice, which was said to have existed 14 days, and he had had sickness and nausea in the mornings, his stools had been pale and the urine dark brown in colour. There had been slight pain in the upper abdomen. He mentioned that he had been using dope at the Hendon aeroplane works; deceased's own view was that dope was made of collodion, chloroform, ether, and acetone, and he said that ten other men had also complained. Patient had a temperature of 99·6°, pulse 96; liver enlarged, no sign of anæmia, no sign of alcoholic excess, nor of gall-bladder disease. The diagnosis he made was jaundice due to the action of some poison on the liver. He thought it probable that some constituent of the dope used was responsible for the illness. He did not see the patient again. On Dec. 4th he received from the coroner's officer specimens of material. The first was marked A by Dr. Willcox; it was an 8 oz. bottle, corked, sealed, and labelled "Dope from Aircraft works, Hendon, in case of Gilbert Moody, G.W. 26/11/14." The other was marked B, and was a 5 oz. corked bottle labelled "Dope from Aircraft works, Hendon, in case of Gilbert Moody, 2/12/14." Their contents he found to be a solution of compound of cellulose in a mixture of methylated spirit, acetone, benzene, and tetrachloride of ethane. He distilled some of the dope, and found that the bulk of the liquid of the dope distilled over between 63° and 80° C. The liquid was volatile. The vapour it yielded on evaporation was 1·91 times as heavy as air. On Dec. 4th he made a personal examination of the Hendon premises with Dr. T. M. Legge, of the Home Office. Mr. Pettit, manager of the factory, afforded him every facility for the inspection, and gave him the fullest information on every point, for which he felt greatly indebted, since the information so given greatly facilitated his investigations. He was at once struck by the manner in which the dope vapour hung about; even at a distance of 30 yards from where the dope was being used one would walk into air strongly impregnated with the vapour; this was explained by its density being twice that of air; heavy vapours mixed only slowly. The ventilation of the building was by the "plenum" system, a very good system for ordinary ventilation, but not for heavy vapours such as dope vapour. On Dec. 5th he received from Dr. Legge samples of each of the respective liquid constituents of the dope varnish, in separate bottles. They were benzene, acetone, methylated spirit, and tetrachlorethane. He decided to make careful animal experiments in order to determine if any of these constituents of dope was likely to cause harmful effects on the liver. White rats were selected as being the most suitable animals. For each experiment a glass chamber was selected, in the bottom of which was placed daily one-third of an ounce of the liquid to be tested. A perforated platform was put across the middle of the chamber, and on this the animal was placed, the upper part of the chamber being covered with a perforated zinc roof. The animals were kept in the glass chambers eight hours per day for a week. The liquids separately tested were dope, tetrachlorethane, acetone, benzene, and methylated spirit. The rats after being kept in the dope vapour and those kept in the tetrachlorethane vapour became drowsy, and remained drowsy for some time after removal. More than an hour after removal elapsed before they fed and became active again, but they did not gain in weight during the week's treatment, as did the other animals. In the acetone experiment the animal was drowsy while in the vapour, but on removal it became lively and normal, and gained weight. In the benzene experiment the animal was drowsy, but was normal on removal, and gained in weight. The animal placed under the influence of methylated spirit was not adversely affected. After seven days' treatment the animals were killed. Post-mortem examinations on them were made by Dr. B. H. Spilsbury and himself. The tetrachlorethane rat showed marked changes in the liver to the naked eye—signs of fatty degeneration and bile staining. The dope rat showed liver changes similar to the preceding, but less marked. In the benzene, acetone, and methylated spirit experiments no changes were seen by the naked eye in the organs of the animals. Dr. Spilsbury made careful microscopical specimens of the organs of the rats, and he had examined the specimens with him. In the rat exposed to tetrachlorethane vapour very marked fatty degeneration and cloudy swelling were present in the livers and kidneys. In the rat exposed to dope vapour marked fatty degeneration and cloudy swelling were present in the livers and kidneys, exactly similar to the changes caused by tetrachlorethane, but not quite so advanced. In the rats exposed to the vapours of acetone, benzene, and methylated spirit respectively no fatty degeneration or cloudy swelling was present; liver and kidneys were normal.

Dr. Willcox had had other experience of a tetrachloride of ethane; he worked at it five years ago in connexion with a shampooing mixture, but that was tetrachloride of carbon. The action of the two was very similar. These organic compounds ran in series, and the series above the tetrachloride of carbon was the tetrachloride of ethane. Five years ago he made experiments on tetrachlorethane simply as a matter of interest to himself, and at that date he formed the opinion that it was a powerful tissue poison. The experiments he had now carried out confirmed the opinion he formed in 1909; the latter work was specially related to dosage. He had the animals kept successively in air containing known percentages of vapour, and the effects from tetrachlorethane he found to be largely dependent on the dosage. In his opinion, air containing only a small trace of tetrachlorethane would not be harmful, but air containing appreciable quantities was harmful, especially if inhaled for long periods. He would not like to commit himself as to what percentage commenced to be harmful; if there was not sufficient in the factory to be smelt it would not be harmful, but he did not feel prepared to state the converse, that if the preparation could be smelt it was injurious. In answer to the coroner, he agreed that in the case of coal gas a proportion which would not be perceptible to the nostrils would be poisonous. He examined the microscopical work of Dr. Spilsbury, and found there was a remarkable destruction of the liver tissue, which might be a consequence of the preceding fatty degeneration. In the deceased the liver and gall-bladder were reduced in size, the former weighing only 34½ oz., and there was a condition of subacute hepatitis. It was the result he would expect from the fumes, especially after exposure during weeks, because these liver changes and shrinkages of cells required time to become established. Asked by the coroner whether removal from the work for a time would cause the effects to cease in the man, he replied that it would not necessarily, because the exposure already undergone might have so damaged the liver cells that they would die and their place be taken by fibrous or scar tissue. That took place in the liver of Gilbert Moody. A man who had only slight fatty degeneration of the liver cells would probably recover if removed from the vapour. It was a question of dosage. The sequel of long exposure to the vapour would be cirrhosis of the liver. From having seen the man Moody at hospital, and from the experiments he had made and his examination of the microscopical sections, he did not doubt that the cause of death was heart failure consequent on degeneration of the liver caused by tetrachlorethane present in the cellulose varnish used by Moody, and to which he was exposed during life. He had investigated the other cases of illness at the works, and had carefully examined nine of them, eight at St. Mary's Hospital and one at the man's home. The symptoms were common to all.

The coroner asked for a statement of those symptoms because of the importance of the matter and the guide which they would be to those engaged in the industry. Dr. Willcox replied that the symptoms were drowsiness while at work, loss of appetite, nausea, vomiting, headache, a peculiar taste and an irritation at the back of the throat, jaundice, with pale stools and high-coloured urine, generally constipation, but no anæmia. If the men complained of being "run down" it would not be because of anæmia. In a few of the cases the patients became delirious and severely ill. In one case there was conjunctivitis without ulceration. In several cases the symptoms disappeared, but on returning to the work they speedily returned and were in an aggravated intensity. One of the patients was very ill at the present time; there was severe dropsy of the abdomen owing to the shrinkage of the liver. When at the aeroplane factory he, Dr. Willcox, had a chat with many of the workers, some of whom he found to be suffering from unmistakable symptoms of commencing dope poisoning. They were not jaundiced, but they had loss of appetite, nausea, and a tendency to sleepiness. He believed the case of Moody was the first one which had drawn definite attention to the danger connected with dope. He believed the illness could be entirely avoided by making proper arrangements. That, however, was a matter for the Factories Department. He did not think the deceased would have died if he had not been engaged in this particular work; he did not regard the death as a natural death. Asked as to the influence of age on the symptoms, he said he could give the ages of the patients, but was not prepared to say what the influence was. Owing to the density of the vapour he would expect a man of short stature, such as the deceased, to be more affected than a tall man. He was sure the illness under inquiry was not catarrhal jaundice. A patient with catarrhal jaundice was only mildly ill; he was yellow, but felt well; his pulse was slow and temperature normal.

Answering Mr. O. Osborne, appearing for the British Emalite Company, Dr. Willcox said he believed tetrachloride of ethane was used in rubber factories, but he had not encountered cases of poisoning by the substance until this one. Asked as to the injurious effect of leaving open tins of dope about the factory, he said it was not a question of open tins, but of having the substance spread over a large surface; it would not evaporate very quickly from tins. If proper precautions were used to get rid of the vapour, it would be safe to use dope. Now that the cause of the trouble was known, he believed it could be removed. Dr. Legge would speak with better authority as to the means. It was not only people who actually used dope who were taken ill, but men working at a distance off were affected also; the vapour spread. Three men were taken ill who were working 60 or 70 yards from the doping. These were mild cases. When walking along one suddenly encountered a cloud of the vapour, as detected by the smell. Answering Mr. Cousins, a factory inspector, he said the tetrachlorethane would be the least volatile of the dope constituents; its boiling point was 147°. Mr. Cousins also asked whether the poison would be more in evidence in proportion as it dried. Dr. Willcox replied that he had thought so, but he did the distillation, and was not sure that it was so. He tried to separate the tetrachlorethane by fractional distillation, but found the vapours went over together. The proportion of tetrachlorethane was something like 10 per cent. The fumes given off from the dope consisted of a uniformly mixed vapour. In answer to the foreman of the jury, he agreed that a fan placed in the ordinary way would have but little effect in clearing away this heavy vapour; it would be necessary for doping to be done in a separate chamber with separate fans.

Evidence as to the Conditions in Works and Preventive Measures.

Dr. T. Morison Legge, Inspector of Factories, Home Office, spoke of having visited the factory twice—namely, on Dec. 2nd and two days later with Dr. Willcox. He found that the premises, originally an omnibus depôt, had been adapted to the present purposes in the early summer. He produced a plan. He could not state the exact superficies, but it would be about 60 or 70 yards by a little more in length—a very open shed, not divided off, but all open to the same atmosphere. There was a double-ridged roof, and glass all along the roof, from which the principal light was obtained; there were windows on the side wall and openings in the end gables. There was a natural system of ventilation arranged for by three lantern louvred openings in each of the ridges. Mechanical ventilation was arranged for on the "plenum" system—i.e., a high-pressure fan driving air which had been warmed into the factory along well-defined tapering trunks, with subsidiary branch ducts at intervals, so distributing the warm air all over the factory. At the time of his visit, however, it had broken down and was not running at all, and he understood that this was not the only occasion on which it had been defective in that respect; it had not been by any means always running. The system was good under ordinary circumstances, but for drawing these fumes away it was thoroughly bad. Preferably the doping area should be shut off from the rest of the room, with adequate inlets to supply volumes of air to replace that drawn off. He considered that this would obviate the danger from the fumes. He wished to utter a caution: that this volume of air mixed with inflammable vapours, such as acetone, might form an explosive compound, and this might be set alight if sparking were possible from an electric fan. Therefore the motor driving the fan would have to be explosion-proof. Or the connexions with the fan could be placed outside. Tetrachloride of ethane in itself was non-inflammable, but he could not say what would be the effect on the varnish for aeroplane wings of removing the tetrachloride of ethane; that was a technical point. The Factory Act provided that if a material had been proved to be dangerous, the Secretary of State had power to take certain steps: either to prohibit its use in the factory, or to take such measures as would remove the danger. The Factory Department would certainly see into the matter.

In answer to the coroner, Dr. Legge said he considered that for the 400 men employed there was very insufficient sanitary accommodation, and he thought that predisposed to some extent to this condition. There were but four sanitary conveniences available for the 400 men; and when he went into the vestibule of the lavatory he found quite ten men awaiting their turn. Such interference with bodily functions would predispose to a greater effect of the poison. He agreed that personal idiosyncrasy would play a part, but this was in the region of surmise, and he did not think the point could be pressed too closely. Apart from jaundice, a certain number of the men had been suffering from gastric disturbance; and he understood that a number had left, without giving any reason, because they found it disagreeing with them. He noticed an odour immediately on entering the main gate, and this was much more marked where the doping was in progress. Quick drying was the great object aimed at. Asked whether he found the people in the factory were generally in a healthy condition, he replied in the negative, for when questioned a history of gastric attacks was elicited from several. Some of the men looked decidedly run down. He visited the factory of the Emalite Company, and there was very little smell indeed at the time of his visit; the air seemed fresh, and his attention was called to the volume fan placed in the wall at a height of about 12 feet. The three men employed were quite healthy. But the mixing was carried out in closed-in drums, so all the exposure the men got was in transferring the ingredient from the drum into a jug and putting that into the revolving mixer. The ingredients were made elsewhere. He visited the factory where the substance was manufactured some years ago because it was a new and important industry. He was told by the person in charge that the substances were narcotic in their action, but not toxic. He did not find in the factory at that time evidence of injury. Subsequently complaint was made of the effects where certain compounds similar to tetrachloride of ethane were used, and last summer one of his colleagues investigated an illness attributed to their effect. No jaundice was noticed by him. This aeroplane industry was the first he had known in which the tetrachloride of ethane was used. But they had come across other and analogous compounds used for dissolving fat out of seeds, but not tetrachloride of ethane. In the similar kind of case referred to partial unconsciousness was caused, but not jaundice. He received from Mr. Pettit the names of 16 men at the Aircraft factory and their addresses, and he tried to see as many as he could in different parts of London. He also saw their medical men, and in that way he arranged for six of those men to go to St. Mary's Hospital to be examined by Dr. Willcox. He had visited other premises where other substances were used for a similar purpose. They were mixed in much the same way as described but practically in the open air, and there was no evidence of illness among the men who did the mixing. He had visited seven aeroplane factories besides the Aircraft one. In one the evidence he received satisfied him that a man whom he did not see was suffering in the same way as the cases he had seen in London. In another factory, where the work was largely done by young women and girls, he examined 16 or 17, and found that one had been away this year for jaundice and congestion of the liver. She had unmistakable evidence of the effect of dope. In most of the cases he had referred to the dope used was a different one, but he believed the ingredients were much the same.

He agreed with Dr. Willcox that without the tetrachloride of ethane there would have been no effect, he said the other vapours present would cause headache and some giddiness, but he would not have expected jaundice to be caused. In none of the other factories he visited were the conditions quite the same as at the Aircraft; the others had the doping done in a partitioned-off apartment. At the factory where he found the least effect more attention had been paid to ventilation than in any other; they had no fans, but four wide Tobin's tubes, and they kept the windows open; they also had ventilation through the ceiling. But there was not nearly as much dope used in them. One shed had been built specially high to allow of the escape of the fumes, in ignorance of the fact that the fumes were twice the weight of air. That there was not serious illness at the Aircraft factory before September he thought was because the employees had not had sufficiently big doses; moreover, it required some time for the symptoms to develop; in this fatal case six weeks. One case he discovered dated back to last February.

Asked what he suggested in order to render doping safe, he recommended that the doping should be done at one end of a shed, in a portion which had been partitioned off from the remainder of the building; that the fume should be removed by volume fans placed near the ground level, protected against possible sparking, and that there should be efficient inlets opposite to where the fan was working; also that no man should be working between the fan and where the doping was being carried on. He thought that none of the men should be allowed to eat their meals in the room where doping was done. In the other places he had visited either mess-rooms were provided on the premises or the doping room was locked up during meal times. He did not think the wearing of respirators would be practicable. Similarly impracticable perhaps was the suggestion that the men engaged in doping should, like firemen, wear a helmet into which air could be forced from the outside. Of course, if some substance could be substituted for the tetrachloride of ethane, so much the better. The process was dangerous as carried out by the Aircraft factory. He agreed that if a man was early affected and was removed, the effects would pass away. He would not say that a man who had once been affected at the works with jaundice should never go back; but he must wait until his recovery was complete. The girls engaged in the work, he had noticed, had a very bright complexion, which was commonly regarded as a sign of robustness; hence it might be deceptive and result in the premonitory symptoms not being suspected. He agreed as to the cause of death in the case of Moody, but without the evidence of Dr. Willcox he could not have said what constituents were harmful.

Dr. Bernard Spilsbury said that what Dr. Willcox found in the case of the man Moody had confirmed his previous opinion that the liver was the seat of advanced hepatitis, and the other organs were healthy apart from secondary changes due to the toxic condition. The investigation had not only confirmed but had enlarged his previous opinion.

The Coroner thanked the scientific witnesses for the clear light which they had shed on the case, and the jury, without retiring, returned a verdict in accordance with Dr. Willcox's conclusion: "Accidental death, caused by heart failure, consequent on degeneration of the liver caused by tetrachloride of ethane present in the cellulose varnish dope, to the vapour of which he was exposed during life at the Aircraft works, Hendon." The foreman said the jury wished him to express their thanks to Dr. Spilsbury and Dr. Willcox for the interesting evidence which they had given, and they hoped the investigation would be the means of preventing further deaths from occurring in this industry.

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Lodging and Accommodation of Hop-pickers, by Dr. REGINALD FARRAR.[1]—The writer of this interesting report has made himself a specialist in all matters relating to the conditions of life of navvies, fruit-pickers, pea-pickers, hop-pickers, and other classes of peripatetic labour, and his last addition to the Local Government Board Reports on these subjects gives a very complete description of the industry of hop-picking and the sanitary questions arising out of the influx of pickers into hop-producing areas in different parts of the country. Dr. Farrar had previously reviewed this industry in a report issued in 1907, and since then the Local Government Board has directed frequent inspections, and pressed the local authorities concerned to make bye-laws, particularly by inquiring at hop gardens before the season begins as to the sufficiency of the accommodation which will be available. Kent is, and has always been, much the most important of the hop-growing counties, but hops are grown also in Sussex, Hereford, and Worcester, while small areas are under hop cultivation in a few other parts of the country. The acreage under hops steadily diminishes, but this is in part compensated for by intensive methods which secure larger yields per acre. The yield of hops in different seasons is very variable, and a single year may often leave the grower with a heavy deficit, to be made up by large profits in a better year. Hop cultivation thus in these days requires capital, and smaller farmers and growers tend to get squeezed out of the industry. In some years the imports of foreign hops have constituted more than half the total supply available for the brewers, thus increasing the uncertainties of the trade. Much is now being done, however, by cold storage to enable the surplus of one year to be carried over to the next, and so steady the market. These considerations on the whole make it easier for the accommodation of hop-pickers to be improved. Measures can be expected of large traders which can hardly be followed by small farmers, and there is now evidence that those who neglect to look after their workers are finding an increasing difficulty in getting the labour they require. Few sanitary questions arise in those areas where the hop-fields are stripped by the local population, with the aid of friends whom they invite for the hopping season. The

[1] Reports to the Local Government Board on Public Health and Medical Subjects. New Series. No. 99. London: Wyman and Sons, Fetter-lane. Edinburgh: H.M. Stationery Office. Dublin: E. Ponsonby. Price 6*d*.

"foreign" pickers, on the other hand, come to the hopfields in thousands from London and other towns; Dr. Farrar estimates them at about 70,000 "full" pickers and about as many young children annually. The London contingents include a higher proportion of men than those which are found in the western counties, where the great majority are women. Dr. Farrar controverts a popular belief that hop-pickers are the "lowest of the low"; he finds the "foreign" pickers generally an orderly, self-respecting class of people, often coming from decent homes, though clad in their worst garments for the occasion. He has a good word also for gipsy pickers. The habitual vagrants, on the other hand, who find their way to the hopfields are often a source of disorder and uncleanliness. They fill the casual wards of the Kent workhouses in anticipation of the hopping season and are a considerable burden on local rates, being only in demand by the farmer who wants people who will sleep and feed somewhere without his being troubled. The children of the "foreign" pickers probably get benefit to health in most cases, but as there are often no facilities for washing they sometimes return to towns in a very dirty or verminous condition, and in camps not properly scavenged they may suffer severely from diarrhœa. They suffer also from there frequently being no opportunity of drying wet clothes. Apparently hop-picking is not looked upon with favour by most educational authorities, though it may be noted that Dr. Mary Williams, reporting in Worcestershire at an examination of 500 children after the hop-picking season of 1911, considered they were in most cases much better physically for the change, and that the children who came back with body lice were generally children to be expected at any time to have body lice. If the educational authorities could extend their supervision of children so as to secure that they were visited and reasonably looked after they would probably do better by encouraging the taking of children hop-picking than by putting obstacles in the way. Dr. Farrar reviews in detail the accommodation now generally made for pickers in farm buildings, tents, and huts. It is curious to read that properly roofed pig-styes, if cleaned and whitewashed, are often in demand and are preferred by the pickers on account of the greater privacy which they afford when compared with large barns and outhouses. As a rule tents are undesirable; they are used by people who do not know how to manage a tent, they are seldom waterproof, and frequently families are closely herded together in them and lie on damp ground. It is unfortunate that under existing powers their use cannot be prohibited by bye-laws. By degrees a good class of hopper hut is being introduced into many hop gardens, and there can be no doubt of their superiority, provided that they are treated as places for short periods of occupation and not allowed to be used throughout the year as rent-free dwellings. Dr. Farrar makes various suggestions, such as the provision of a few shelves and pegs for hanging up clothes, the continuation of the roof to make a shelter in front of the huts, better window openings, and the like, which need only to be pointed out for their advantage to be apparent. Indeed, in this matter, as also with the remedies necessary to prevent bad food being hawked in the encampments, the provision of cheap cooking shelters, and similar questions, the report will be invaluable to those who are desirous to improve matters but do not know where or how to begin. It may be concluded from the report that the majority of growers and most of the local authorities concerned are anxious for such improvements, and it is to be hoped that the Local Government Board, by its inspections, and if necessary by giving greater powers to local authorities in the matter of bye-laws, will see that those who are considerate for the accommodation and health of the hop-pickers do not suffer by continuance of neglect on the part of those who are apathetic Really bad cases of insanitary hoppers' camps, places where there is no water-supply within a quarter of a mile, no scavenger, no cooking shelter, and only wet ground or floors to sleep on, ought to be dealt with by sharp measures. Hoppers cannot, perhaps, expect such a high standard of accommodation as the Government is giving to German prisoners, but at least the contrast need not be too marked.

SIR WILLIAM COLLINS has been elected President of the University of London Graduates' Association in succession to Lord Moulton of Bank.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Frederick James Burns has been placed on the Retired List (dated Dec. 9th).

The following appointments have been notified:—Fleet-Surgeon: E. C. Ward to the *Pembroke*, for R.N. Barracks. Temporary Surgeon: J. G. Bailey to Hythe and for duty in Folkestone.

ROYAL ARMY MEDICAL CORPS.

Sir Alexander MacCormick is granted temporarily the honorary rank of Lieutenant-Colonel whilst serving with the Australian Medical Unit (dated Dec. 19th).

Major Frederic W. Lamballe is placed temporarily on the Half-Pay List on account of ill-health (dated Dec. 19th).

The undermentioned to be Lieutenant-Colonels:—Dated Nov. 27th: Major Hubert A. Bray (and to remain seconded) and Major Thomas McDermott.

The undermentioned to be temporary Lieutenants:—Dated Oct. 9th: John Leeper Dunlop. Dated Oct. 17th: Douglas Edward Crosbie. Dated Oct. 21st: George Whitfield Rea. Dated Oct. 29th: Winslow Seymour Sterling Berry. Dated Nov. 14th: Thomas William Gerald Hogg. Dated Nov. 16th: Samuel Patterson Rea. Dated Nov. 23rd: Norman Colum Patrick. Dated Nov. 26th: Norman Clotworthy Graham. Dated Nov. 28th: Thomas Grimson. Dated Dec. 1st: Alexander Harper Robinson Duncan. Dated Sept. 26th: Alexander Bremner. Dated Dec. 1st: John Hanson, James Jameson Dwyer, William John Fitzgerald Mayne, Mackenzie Douglas, John Cecil Lynmore Day, Timothy Meagher, John Douglas Cherry, Patrick Joseph Maguire, and Walter Eustace Adam. Dated Dec. 2nd: Charles Vincent Mackay. Dated Dec. 4th: Humphrey Meigh Stephenson, Arthur Leslie Harmsworth Rackham, William George Helsby, Norman Frankish Graham, Alexander Beck Cluckie, John Macarthur, William Hugh Brodie, Harry Morgan Gilmour, Henry Caplan, James Potter, and John Anderson. Dated Dec. 6th: Maurice Henry Whiting, Stephen Rowland, Colin King, Donald Duff, Frank Hartley, Thomas Engleheart Amyot, Cyril Guy Whorlow, Frederick Waistell Hird, James Rowland Rigg, Ernest Lloyd Shelton-Jones, Walter Joseph Ronan, and Edward John Stubbs.

Lieutenant Francis H. Storey relinquishes his temporary commission (dated Dec. 7th).

TERRITORIAL FORCE.

Army Medical Services.

Captain John B. Yeoman, Deputy Assistant Director of Medical Services, to be Major.

Royal Army Medical Corps.

1st South Midland Mounted Brigade Field Ambulance: Lieutenant Cyril R. Wallace, from the 2nd South Midland Field Ambulance, to be Lieutenant.

2nd East Anglian Field Ambulance: Major James M. G. Bremner to be Lieutenant-Colonel (temporary).

1st Home Counties Field Ambulance: Captain Antony A. Martin, from Attached to Units other than Medical Units, to be Captain.

1st East Lancashire Field Ambulance: Gordon Lisk Trelawney Stoker to be Transport Officer, with the honorary rank of Lieutenant.

2nd East Lancashire Field Ambulance: Captain Alexander Callam to be Lieutenant-Oolonel (temporary). Emor Reuben Cooper to be Lieutenant.

1st London (City of London) Field Ambulance: Major Edmond W. St. Vincent-Ryan to be Lieutenant-Colonel (temporary).

1st North Midland Field Ambulance: Arthur Heath to be Lieutenant.

2nd North Midland Field Ambulance: Samuel Russell Foster (late Cadet Serjeant, Belfast University Contingent, Senior Division, Officers Training Corps) to be Lieutenant.

1st West Riding Field Ambulance: Herbert John Robson (late Captain, Northern Command, Royal Army Medical Corps (Volunteer), Leeds Companies) to be Captain. Hugh Roger Partridge to be Lieutenant.

3rd Northern General Hospital: John Broadley to be Captain. Archibald Young (late Major of the Unit) to be Captain.

1st Southern General Hospital: The undersigned to be Lieutenants: Stephen Grange Askey, Alfred Percy Phillips, Percival Courtnay Cole, and Ambrose Wilfred Owen.

1st London (City of London) Sanitary Company: Private Charles John Dickenson Gair, from the 23rd (County of London) Battalion, The London Regiment), to be Lieutenant.

2nd London Sanitary Company: Francis Samuel Carson to be Lieutenant.

West Lancashire Clearing Hospital: William Percy Moffet to be Lieutenant.

2nd London Clearing Hospital: Eric Stuart Taylor to be Lieutenant.

1st South Western Mounted Brigade Field Ambulance: Leighton Hill Hay to be Lieutenant.

Sanitary Service: Lieutenant-Colonel Archibald K. Chambers is seconded.

Attached to Units other than Medical Units.—To be Captains: Julius Henry Beilby, late Surgeon-Captain, Worcestershire (Queen's Own Worcestershire Hussars) Imperial Yeomanry, Lieutenant Daniel R. Kilpatrick, Thomas Sanders Worboys (late Lieutenant, Royal Army Medical Corps, Territorial Force). Lieutenant John T. Shaw resigns his commission on account of ill-health. Lieutenant Edward C. B. Paul is seconded. To be Lieutenants: George Crawshaw and Frederic Ernest France.

Obituary.

HERBERT VICTOR WENHAM, M.B., B.S. LOND., F.R.C.S. ENG.

THE cause of medical education in China has received a great blow in the death of Dr. H. V. Wenham, of the Union Medical College, Peking, from septic pneumonia. He was a distinguished scholar of St. Bartholomew's Hospital, and in 1902 graduated M.B. Lond. as well as becoming M.R.C.S., while in the following year he took the B.S. Lond. and the F.R.C.S. Eng. After three years' further study (mostly in house appointments at St. Bartholomew's), equipping himself for the object he had in view, he went to China and at once began to search for the best outlet for his energies as medical teacher. He knew the crying need that exists for trained Chinese doctors able to introduce the benefits of scientific medicine and surgery among the millions of this great country suffering to such an incalculable and unnecessary extent from disease improperly treated. The Union Medical College was then starting on its career, and Dr. Wenham saw that its scheme of giving as thorough a medical education as possible was just what he was seeking, and he offered his services, which were at once accepted. From that time till his death he worked hard and incessantly among the students. Possessed of high ability he very soon became a fluent Chinese scholar, able to read and write Chinese, also to lecture and demonstrate in that language. When the epidemic of pneumonic plague appeared in North China he inspired his students with enthusiasm for the opportunity which it gave them of showing their true worth, the result being that a number of them volunteered as nurses and medical helpers, working well throughout the epidemic. Two of them became infected and died. Of these two one rushed back when he fell ill to Peking to Dr. Wenham, his master, who nursed him himself till death came. In the most fearless way he searched out and isolated at once any other cases, and it was due primarily to Dr. Wenham's exertions that a big epidemic of this highly infectious disease was prevented in Peking. Later on, during the Revolution he took the field at the head of his students as a Red Cross unit and rendered fine service to the sick and wounded during the fighting round Hankow. Modest and self-effacing to a degree, he was loved by his students, who were able to judge his character during the continuous hours he spent among them. He was one of the leading members of the College Faculty, and was constantly to the fore with new thoughts and methods for raising the standard of medical education. A thorough admirer of his old school, his constant aim was to bring the College and its new hospital up to "Bart's" standard. This meant hard work, but hard work and a brave example made up his world. During his nine years in China he not only worked entirely without pay, but contributed from time to time to the funds of the hospital when necessity arose. In order to enable himself to do this he lived in a modest way, denying himself wherever possible.

In Dr. Wenham the British medical profession and the Christian missionary world in the Far East have lost a most valuable representative. To quote a Chinese writer, who expressed the feelings of Chinese and foreigners alike towards him: "None who came in contact with him but felt the great charm of his unique personality, his purity of motive, his devotedness, sincerity, and abhorrence of sham or careless work, which were the outstanding features of his work." He was a warm-hearted friend of the anti-opium movement, and last year paid a visit to England, with General L. Chang, to plead the cause of the movement at home. He died in the beautiful hospital largely built by his exertions, and his funeral was attended by his devoted students and fellow workers, Sir John Jordan, the British Minister, and a large number of foreigners and Chinese.

Dr. Wenham left a widow, for whom much sympathy is felt.

Correspondence.

"Audi alteram partem."

THE SHORTAGE OF MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—The registrars, deans, and other officers of the schools of medicine and of approved scientific institutions throughout the United Kingdom have been good enough to furnish me with returns showing the number of medical students in attendance this session as compared with the number in attendance last year. As the statistics have an important bearing on many questions touching the future supply of qualified practitioners for the service of the country, I would ask you to publish the following figures:—Decrease in enrolments October, 1914, as compared with preceding year: First-year students, 56 fewer; second-year students, 237 fewer; third-year students, 237 fewer; fourth-year students, 211 fewer; fifth (and higher) year students, 300 fewer.

The aggregate number of medical students now pursuing their curriculum with a view to qualification is thus about 1000 smaller than in 1913.

Unless many senior students return to their studies within the next few months the result will be that the number of young qualified practitioners added yearly to the ranks of the profession will during the next few years be from 200 to 300 less than before. This is equivalent to a diminution of about 25 per cent. of the average number annually added to the Medical Register on qualification. The number annually removed from the Register by death or otherwise has for some years past been about 800.

In view of the additional losses among senior practitioners due, directly or indirectly, to the war, the prospective diminution of our reserve supply calls for serious consideration.

I am, Sir, yours faithfully,

DONALD MACALISTER,
President, General Medical Council.
Medical Council Office, Oxford-street, W., Dec. 19th, 1914.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

To the Editor of THE LANCET.

SIR,—At a recent meeting of the Council of the Brussels Medical Graduates' Association it was resolved to send out a circular to all British practitioners with Belgian medical degrees specially asking support for the above fund. It was hoped that they would be willing to assist this association in getting together a considerable sum that might be presented to the above-mentioned fund in the name of Belgian medical graduates generally.

The appeal has been fairly successful, but the council desires that at least 100 guineas should be collected before the contributions are handed over, and this amount has not as yet been quite gained. May I ask through your columns any Belgian medical graduate whom our circular may not have reached, or who has not already subscribed to the fund, for a small subscription for the above purpose?— I am, Sir, yours faithfully,

MAJOR GREENWOOD,
Treasurer, Brussels Medical Graduates' Association.
243, Hackney-road, N.E., Dec. 20th, 1914.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—In reference to your remarks about the omission of the "abroad" section of the "Medical Directory" we desire to point out that the compilation of this list is one which has presented numerous problems to those who have had to undertake it. It has always contained only a selection of names, and it is not easy to know where to draw the line. We think the list has only been useful to a small proportion of the users of the Directory, but they are worthy of consideration, and the whole matter has again our serious attention.

We are, Sir, yours faithfully,

London, W., Dec. 19th, 1914. J. & A. CHURCHILL.

CHLORALOSE AS AN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—Professor D. T. Barry's letter in THE LANCET of Dec. 12th draws attention to a much neglected hypnotic. Anhydroglycochloral, better known by the fancy name chloralose, was prepared in 1892 by M. Henriot by combining chloral hydrate and glucose. He sought to produce a hypnotic to replace chloral. The therapeutic and physiological properties of the drug were investigated by M. Ch. Richet, who found that in doses of 0·3 grm. per kilo of the animal sleep came on and lasted an hour and a half, and although it was profound all the reflexes were not only preserved but exaggerated The anæsthesia was complete, but the least external shock produced twitchings of a tetanic character. When the dose was raised to 0·50 grm. per kilo death resulted by arrest of the respiration. Many French physicians recommend its use in all cases in which chloral would otherwise be prescribed; and as an anæsthetic in strong doses, 0·50 grm., Dr. Héricourt and Dr. Ch. Féré consider it is indicated in all cases of weak cardiac action, and find that it is well borne by the stomach. Withal it should be administered with great caution to hysterical patients, to whom it should at first be given in small doses, say 3 grains, and the total amount in the day ought not to exceed 8 grains. In epileptics M. Féré has, however, given as much as 20 grains without causing any unpleasant results. The hypnotic, however suffers from the great disadvantages of having a bitter nauseous taste and being sparingly soluble in water. M. Bain prepares an effervescent form of the drug which lessens these disadvantages. The drug is, however, generally given in cachets. But as Dr. J. M. Fortescue-Brickdale ("Newer Remedies") has included the drug in his list of dangerous hypnotics, and states that, contrary to the view of French physicians, it is a cardiac depressant, it is highly improbable that it will come into general practice. A much less toxic chemical is trichloracetyl-dimethylphenyl-pyrazolone, also known as chloral-antipyrine, and by the fancy name hypnal, which is produced by the action of chloral-hydrate on antipyrine. Dr. Burdet recommends it as a hypnotic in insomnia, due to pain or the irritation of coughing, in 7 grain doses. It occurs in crystals, is soluble in water, and is devoid of taste and smell.

I may add that some years ago I prescribed chloralose, but unfortunately the drug was unknown to the compounders, and my patients unconsciously took chloral.—I am, Sir, yours faithfully,

Dec. 12th, 1914. GEORGE FOY.

INSOMNIA AND SUICIDE.

To the Editor of THE LANCET.

SIR,—Those oculists who pay special attention to the symptoms resulting from refractive errors will welcome the paper by Mr. C. E. Pronger under the title of "Insomnia and Suicide" in THE LANCET of Dec. 12th.

In my experience some of the results I have obtained from the proper correction of errors of refraction, in cases similar to those he mentions, have appeared so extraordinary that I have hesitated hitherto to accept them as being due entirely to the wearing of suitable glasses, but with the evidence given by the author of the paper it seems I am justified in considering these effects are correct. There is no need for me to narrate case histories, and I have the notes of two patients in particular who threatened to commit suicide on more than one occasion during their fits of depression, but with the constant wearing of glasses, which fully corrected their errors of refraction, all thoughts of suicide disappeared.

Possibly it would have been still more interesting if Mr. Pronger had given some idea as to the form the errors of refraction in his cases assumed, more particularly in those he mentions. On going hurriedly through my case books I find most of these (which may be almost called "borderland") cases have very low degrees of astigmatism, rarely exceeding 0·75 D., with the axes of the cylinders at different angles—for instance, the axis for one eye vertical, for the other horizontal, or axis for one down and out, for the other down and in, but at different degrees. Sometimes the amount of astigmatism is as low as 0·12 D., and I think these cases will be found often to have the more marked symptoms—in fact, I am inclined to say the lower the error the greater the nerve disturbance. As might be expected, hypermetropes are more often found to be the sufferers than myopes, though the latter are not rare; the patients are to be met with usually in the decade 35–45, and naturally amongst those following sedentary or studious occupations. In estimating the amount of the refractive error it is often necessary to use atropine, so active and vigorous is the ciliary muscle in these patients; on the other hand, it will be needful to re-examine some when the cycloplegic has passed off, as a certain number are presbyopic although the so-called presbyopic age may not have been reached. The glasses prescribed must be worn constantly.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 15th, 1914. REGINALD EVERSHED.

VACANCIES IN THE TERRITORIAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Might I urge the claims of the R.A.M.C. (T.F.) upon the younger members of the profession? Judging by the appeals of commanding officers of Reserve Units for officers, there appears to me to be a danger of the Territorial Medical Service being overlooked. As it is probable that a considerable portion of our Territorial Army may shortly be leaving our shores for foreign service, it is of the utmost importance there should be no shortage of medical officers to call upon when necessary. Might I suggest that a list appear in THE LANCET of units in which there are vacancies. My own unit, the 3rd (Reserve) Northumbrian Field Ambulance, is in urgent need of officers.

I am, Sir, yours faithfully,

O. L. APPLETON,
Major, R.A.M.C. (T.F.), O.C. 3rd (Reserve) Northumbrian Field Ambulance.

Wenlock Barracks, Hull, Dec. 17th, 1914.

*** For some time past notices of vacancies in the Territorial Medical Service have appeared week by week in our "War" column. We are always pleased to help officers in command of units to complete their establishment.—ED. L.

OPEN-AIR TREATMENT FOR WOUNDED SOLDIERS.

To the Editor of THE LANCET.

SIR,—The healing power of the winds of the Heavens is now established beyond all question; but is there not also virtue during winter's stormy nights in the peace and cheeriness of a hot dinner, an armchair, and a blazing fire? A return to the latter after visiting the "open-air hospital" at Cambridge (which has undergone no modification since its inauguration in the dog days) brings wonderings as to what proportion of our medical profession would really approve of the "open-air treatment" at one of the dampest spots in England of those 1250 brave defenders of our hearths and homes who have been sent back from the trenches, wounded and suffering, into the heart of old England at Christmas-time, only to land in a cricket field, now one vast muddy slosh, across which are stretched rows of draughty open verandahs that constitute the hospital! No heating arrangements whatever, no tables, no chairs. (The goodly proportion who are up and dressed take their meals—none too hot—on the edges of the beds.) No matter how bad the weather, there is no way of shutting it out. Nurses in goloshes and with hands all chilblains wrestling with the elements for the possession of surgical dressings. Men just as splendid as ever. When one from a convoy of a dozen frost-bite cases who arrived last week remarked, "What they say I'm suffering from is exposure," there was no vestige of complaint in his tone—merely a desire to communicate a fact we did not seem able to grasp on this side of the Channel. The cases do well and the total results seem as good as those from any other hospital, therefore in spite of the unique discomfort, active intervention is not called for from the point of view of the scientific healing of the wounds. But is that the only consideration? Why if the healing results are not very markedly superior should lads with terrible injuries be deprived of any harmless and obtainable comfort?

I am, Sir, yours faithfully,

ETTIE SAYER, M.B. Lond.

Upper Brook-street, London, W., Dec. 16th, 1914.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

DURING the week the interest in the movement for aiding the Belgian doctors and pharmacists, both those who remain in their own country and those who are refugees with us, has made steady progress. The list of subscriptions which we publish does not bring the record of contributions nearer than the morning of Tuesday last, Dec. 22nd, as the occurrence of the Christmas holidays compels us to go to press early in the week.

The first order for parcels of medical materials is under execution. The goods are awaiting despatch to Belgium by Messrs. Burroughs, Wellcome, and Co., through the agency of Mr. H. Hoover, 3, London Wall Buildings, E.C., Chairman of the Commission for Relief in Belgium. The British Government have not yet given the Commission the necessary licence to export. The parcels will be consigned, on the instruction of the Belgian Committee, represented here by Professor C. Jacobs, to M. Delacre, a well-known pharmacist in Brussels, who has been directed in making the distribution to report the results as soon as possible to the British Committee.

The British Committee have appointed a sub-committee to inquire into cases in this country where small immediate relief is sought, and where it seems right to supplement the regular action in this direction of the British Government.

Dr. F. Howard Humphris, President, Brussels Medical Graduates' Association (8, West Chapel-street, Mayfair, W.), writes:—

> "An appeal in money is being made for those Belgian doctors who are refugees in this country, and this has met already with generous response. There are many, however, who would doubtless prefer to find a home in the family of an English medical man where they could give such services as lie in their power. Up and down the country thousands of homes have already been given to destitute Belgians, and I feel that there must be many medical men in this country who would in this way like to repay something of the debt of gratitude which they owe to Belgium. There are about 140 Belgian doctors at present in England, the majority of whom are in very straightened circumstances, and I feel that it only needs an appeal through your columns to the 30,000 British practitioners to call forth a ready response in the form of an offer such as I indicate."

Dr. Humphris will deal with any correspondence relating to the matter, and put any offers before the Committee of Belgian Medical Men in London, who are endeavouring to assist their compatriots.

Dr. Major Greenwood, treasurer, Brussels Medical Graduates' Association (243, Hackney-road, N.E.), appeals in a letter in our columns to Belgian medical graduates for subscriptions to the Fund.

A meeting of the medical profession in Hampstead, called by the local Division of the British Medical Association, was held in the hall of the Blind School, Swiss Cottage, on Dec. 18th in furtherance of the objects of the Fund for the relief of doctors and chemists in Belgium. Sir Rickman Godlee explained the objects of the Fund, and Dr. D. G. Pidcock moved, and Dr. G. E. Shuttleworth seconded, the following resolution, which was carried:—

> That a fund be established entitled "The Belgian Medical Relief Fund," and that the trustees be the chairman and vice-chairman of the Hampstead Division of the British Medical Association.

The Pharmaceutical Society of Great Britain has been active in various directions in succouring Belgian pharmacists who are refugees, many of whom are in very distressing circumstances.

The following subscriptions to the Fund have been received by Dr. Des Vœux up to Tuesday morning last, in addition to subscriptions amounting to £1888 previously acknowledged:—

	£	s.	d.
Mr. E. Warters	2	2	0
Sir John W. Byers ...	2	2	0
Dr. Clifford Beale	5	5	0
Medical Insurance Agency	26	5	0
Dr. T. W. McDowall ...	5	5	0
Mr. F. Manser...	2	2	0
Mr. G. L. Latour	1	1	0
Dr. Justin McC. McCarthy	1	1	0
Dr. Henry Malet	2	2	0
Sir Edgecombe Venning	3	3	0
Mr. Ernest Osborne ...	1	1	0
Mr. Lionel Scargill ...	1	1	0
Clinical Society of Manchester (per Dr. Price Williams, Hon. Treas.)	25	0	0
Dr. S. M. Salaman... ...	1	0	0
Dr. Alfred C. Warren ...	1	1	0
Miss Helen MacMurchip	0	5	0
Dr. F. Charlesworth ...	2	2	0
Dr. Emma M. Johnstone	5	0	0
Sir Alfred Fripp	26	5	0
North Middlesex Division B.M.A. (first list)—			
Dr. A. M. Bremner	0	10	6
Dr. E. C. Curtis ...	0	10	6
Dr. F. Hasler	0	10	6
Dr. W. Knapp	1	1	0
Dr. W. Mailer	0	10	6
Dr. G. M. Mellor ...	1	1	0
Dr. W. E. Porter ...	0	10	6
Dr. H. F. Staunton	1	1	0
Dr. W. H. Tomlinson	0	10	6
Dr. W. F. Waugh ...	0	10	6
Dr. W. B. Winster...	0	10	6
Dr. F. C. Wood ...	1	1	0
Dr. A. G. Allan ...	0	10	6
Dr. F. Slater Jones	0	10	6
Dr. F. W. Wiles ...	0	10	6
Dr. Johnstone Campbell	3	3	0
Dr. Sidney Davies ...	2	2	0
Dr. G. H. West Jones ...	2	2	0
Dr. Leslie Thorne Thorne	1	1	0
Dr. Archibald Finlay ...	3	3	0
Dr. J. Blyth	0	10	0
Dr. Percy C. Bushnell...	2	2	0
Dr. D. Macmillan	3	3	0
Sir StClair Thomson ...	2	2	0
Dr. Herbert Lucas... ...	2	2	0
Dr. Thos. Redmayne ...	3	3	0
Dr. Constance Long ...	5	0	0
Dr. F. W. Emery	5	0	0
Dr. Chas. W. Chapman	1	1	0
Mr. W. F. Brook	3	3	0
Mr. Clayton-Greene ...	10	10	0
Dr. J. Wiglesworth ...	1	1	0
Mr. F. W. Gamble... ...	2	2	0
Dr. Abraham Cohen ...	1	1	0
Dr. C. H. Joy	1	1	0
Dr. F. Broadbent	2	2	0
Dr. H. Witham	1	0	0
Dr. R. S. C. Edleston ...	1	1	0
"Anon."	1	0	0
Dr. Charles Frier	5	5	0
Dr. W. R. Reith	2	2	0
Sir Arthur Downes ...	5	5	0
Mr. J. A. Symonds ...	0	10	0
National Union of Women's Suffrage Societies, Port Talbot Branch (collected by Dr. Henrietta James)	4	3	6
Mr. E. G. Thorne	0	10	0
Dr. Hugh Playfair... ...	3	3	0
Dr. W. B. Russell	1	1	0
Dr. G. Victor Miller ...	1	1	0
Dr. Arthur C. Black ...	3	3	0
Dr. W. Townsend Storrs	1	0	0
Mr. F. Ashley Rogers ...	2	2	0

Subscriptions to the Fund should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited, and sent to Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments, &c., kindly contributed by the following donors since the publication of the last list:—

Lieutenant-Colonel C. J. McCartie, I.M.S., Kingston, Co. Dublin; Dr. Evers, Faversham; Anonymous; Messrs. Maw, Son, and Sons, Aldersgate-street, E.C.; Dr. Darley Wynne, Clonmel, Co. Tipperary; Dr. F. W. Monsell, Lydney, Glos.; Colonel Joubert de la Ferté, Weybridge; Dr. J. Ross Steen, Ilford; Dr. R. Murdock Matheson, Edinburgh; Dr. Aldersmith, Horsham; and Dr. E. A. Milner, Lancaster.

THE LATE PROFESSOR VAN GEHUCHTEN.

Professor van Gehuchten of Louvain, whose death occurred at Cambridge on Dec. 9th, was a neurologist of world-wide fame. His original work on the anatomy of the nervous system, on staining methods and chromatolysis, on the olfactory and acoustic nerve tracks, and on many other of the most difficult problems of neuro-pathology, proved him to be a great teacher as well as a great investigator and clinician.

BEIT MEMORIAL FELLOWSHIPS.—At a meeting last week of the trustees of the Beit Memorial Fellowships for Medical Research the following were elected Fellows: Edwin Greaves Fearnsides, M.D. Cantab., M.R.C.P. Lond., assistant physician to the Hospital for Paralysis and Epilepsy, Maida Vale, W.; Frances Mary Gore Micklethwait, F.I.C.; and Eward Palmer Poulton, M.B. Oxon., M.R.C.P. Lond., assistant physician to Guy's Hospital. The Fellowships are each of the annual value of £250, and the usual tenure is three years, but an extension of one year may be granted by the trustees in exceptional cases. The following are the researches proposed by the present successful candidates and the places at which they will be carried out: Dr. Fearnsides: (1) To continue the work with Dr. Henry Head, Dr. Paul Fildes, and Dr. J. McIntosh on syphilis of the nervous system; (2) to investigate the intimate anatomical relationships of the meninges and parenchyma of the nervous system in man and animals with a view to the further elucidation of the different behaviour of these structures in disease; (3) to continue investigations on the clinical manifestations of diseases of the pituitary body. Place of research: The London Hospital, E., and the Hospital for Epilepsy and Paralysis, Maida Vale, W. Miss Michlethwait: Chemiotherapeutics, especially with regard to organo-metallic compounds of the nature of "salvarsan," with a study of the metallic derivatives of aminocarboxylic acids and polypeptides. Place of research: Royal College of Science, London, for chemical experiments; Lister Institute, King's College, or Physiological Laboratories, University College, for physiological experiments. Dr. Poulton: Respiration and metabolism in disease. Place of research: Laboratories of Guy's Hospital Medical School.

THE WAR.

The Legion of Honour.

The President of the French Republic, with the approval of the King, has bestowed the Croix de Chevalier of the Legion of Honour upon Captain J. J. O'Keeffe, Royal Army Medical Corps, for gallantry during the operations between August 21st and 30th with the Expeditionary Force.

The Casualty List.

Up to the time of going to press the casualty lists have contained the name of one officer of the Royal Army Medical Corps:—

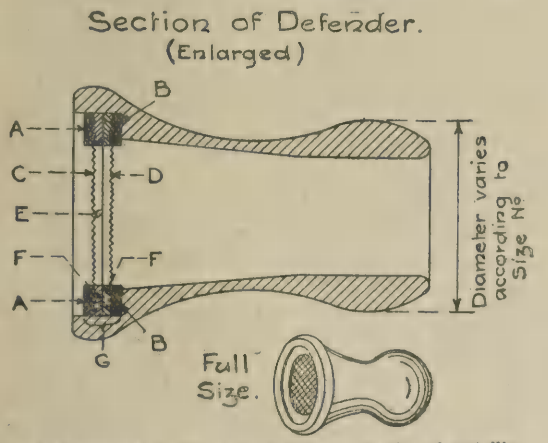
Wounded: Lieutenant R. F. Young.

French Statistics of Wounds in the War.

The Medical Service at the Ministry of War has now made public some interesting statistics from the beginning of the war to Dec. 1st in regard to the results of wounds received during the war in the French Army as follows: Cured and returned to the front, 54·5 per cent.; cured but given convalescent leave, 24·5 per cent.; the remainder include those still under treatment in hospital and a small number of invalided. The death-rate was only 3·48 per cent. Thus more than half the wounded, thanks to the care of the medical service, have been returned to the firing line, while the death roll among the wounded has fallen below the mark of any previous war.

The Mallock-Armstrong Ear Defender.

During the present war so much has been heard of temporary and permanent deafness and distraction occasioned by gun- and shell-fire that it is not surprising that the Mallock-Armstrong ear defender, a device used for several years with complete success under peace conditions to obviate these injuries, is now brought forward to alleviate the very real trouble that affects our active naval and military forces. This ear defender is the invention of Mr. A. Mallock, F.R.S.; it allows ordinary sounds to pass with but very slight loss of distinctness or power, but absolutely prevents any change of pressure from reaching the inner ear. The essential part of this ear defender consists of a very light and sensitive diaphragm of thin material held in the outer part of a short tubular fitting of special construction, which is placed just within the ear; the diaphragm is protected from physical injury, dampness, &c., by a non-corrodible metallic gauze stretched on both sides close to and parallel to it. The diaphragm, thus protected, can only move within the narrowly prescribed limits controlled by the proximity of the gauze, but it vibrates freely to ordinary sounds and transmits these to the ear with little loss. Explosions or other loud sounds momentarily press the diaphragm against the inner gauze—or "stop"—which prevents the rapid change of pressure created by the explosion reaching the tympanum. When in use the senses are therefore left free to receive natural impressions; ordinary conversations, commands or whistles are distinctly heard immediately after firing; and all gun-fire, whether that of machine guns, light field guns, or guns of the largest calibre, is harmless to the ears. In the same way shell-bursts, however close, are rendered equally harmless.



E, The sensitive diaphragm. C, Outer protection of metallic gauze. D, Inner protecting gauze, or "stop." F and F, Spacing-washers between diaphragm and the two gauzes. A A and B B, Inner and outer frame. G, Seven components forming protective drum.

We have asked Mr. Mallock to add a note of his personal experience with the "defender," and this he has done.

"I made this 'ear defender' for my own convenience in 1895 or thereabouts, when I first had much to do with large guns, and found that it was very efficient for the purpose in view. I have worn them for many hours consecutively. After the first few minutes their presence in the ear is forgotten, and I have never known them to cause any discomfort. It is curious when standing in positions where the explosive pressure is high to feel the compression of the body produced by the blast—an effect which is quite lost in the sharp shock received through the ears when the latter are unprotected; at least, this is my own experience. Different individuals differ considerably in their sensitiveness to such shocks, but, as a rule, all who have much to do with firing large guns or even small arms have their power of hearing more or less impaired."

University College, Dundee, and the War.—It is stated that 36 per cent. of the total number of men students normally in attendance at University College, Dundee, are on active service, or are in training with the Regular or Territorial Forces, and the majority of those who remain, though too young for enlistment, are members of the Officers Training Corps. The attendance of students at the College has fallen from 202 in the session before the war to 153 in the present session. There are 67 women in place of 68 the previous year, and 86 men in place of 134.

Antitetanic Serum in France.—Our Paris correspondent writes: "Dr. Bazy on Dec. 14th presented to the Académie des Sciences an interesting communication on the effects of preventive injections of antitetanic serum. Out of a total of 10.896 wounded 129 cases of tetanus occurred. Of these 90, or 70 per cent., died, thus showing the gravity of the disease. Tetanus set in in some cases only two days after the injury, in others as late as 28 days, but the usual term was from six to seven days. It was particularly frequent in certain localities. The preventive action of the serum is beyond dispute. M. Bazy cited a case of 200 wounded, of whom only half received the injection. Out of the hundred injected only one had tetanus, which appeared next morning under circumstances in which the preventive serum had no time to take effect. Out of the 100 who had no injection 18 had tetanus. The character of the wound also exercises a great influence on tetanic infection. The disease appears more particularly as a result of suppurating or 'ragged' wounds produced by fragments of shell and by shrapnel, and is very rare as the result of bullet wounds. However, M. Bazy has seen nine cases of tetanus out of

120 bullet wounds. The injection should be made as soon as possible in a dose of 1 c.c."

Queen's University of Belfast.—It has been decided to hold a special final M.B. degree examination on Jan. 5th to 8th, 1915, in response to a petition signed by candidates who wish to qualify for the war.

Chinese Medicine and the War.—Our Peking correspondent writes: "The reflective effect of the war on China is proving almost disastrous in many ways. Trade is at a low ebb, silver currency has fallen very much, prices have gone up, and in all hospitals the drugs and dressings have increased so much in value as to make them almost prohibitive. Germany had of late years made such great strides in the supply of drugs to China, and given such facilities for prompt delivery of these things, as well as supplying hospitals and medical men with price lists in English and plentiful samples, that many doctors now feel the want of such houses as those of Merck, Bayer, and others. British drug manufacturers have now a great opportunity in the Far East, especially since the fall of Tsingtao, and the expulsion of every German from Hong-Kong, the import capital of Chinese trade. The Chinese of late have shown much appreciation of salvarsan, and every day one has to turn away applicants for it as the stock has now come to an end. Japanese medicine, as is well known, is founded on German lines; every educated Japanese doctor can speak German, they use German instruments, drugs, &c., and read the literature of that country, while they have hitherto for years past sent many graduates to study in German laboratories. Now they all hate the Germans, and it would therefore seem that the present is a great opportunity for British medical schools to come to the front and do what they can to attract both Japanese and Chinese students."

Medical News.

University of Oxford.—The following candidates have satisfied the examiners in the undermentioned examinations:—

First B.M., B.Ch.

Organic Chemistry.—E. A. Crook, W. Gover, R. B. Hervey-Wyatt, C. F. Krige, and R. T. F. D. Roberts.

Human Anatomy and Human Physiology.—J. H. Beattie, E. H. Creed, R. B. Hervey-Wyatt, G. H. Rossdale, J. J. Savage, N. F. Smith, S. C. Varley, and J. P. S. Walker.

Second B.M., B.Ch.

Materia Medica and Pharmacology.—E. W. Bowell, W. H. Butcher, G. J. Evans, G. T. Gimlette, J. M. Guilfoyle, G. A. Maling, and A. L. Watts.

Pathology.—E. W. Bowell, W. Brown, J. B. Cavenagh, R. W. J. A. Cushing, A. G. East, V. T. Ellwood, L. Gameson, F. C. Gladstone, J. M. Guilfoyle, and B. E. Wall.

Forensic Medicine and Public Health—E. W. Bowell, L. R. Broster, W. Brown, R. W. J. A. Cushing, R. C. Fairbairn, B. E. Wall, and H. A. B. Whitelocke.

Medicine, Surgery, and Midwifery.—L. R. Broster, W. Browne, F. W. Browne, C. H. Carlton, V. T. Ellwood, F. C. Gladstone, C. H. L. Harper, G. A. Maling, H. G. Morris, G. S. Robinson, and B. E. Wall.

University of Cambridge.—At a Congregation held on Dec. 19th the following medical degrees were conferred:—

M.D.—H. G. P. Castellain, Trinity.
M.B.—F. G. Rose, St. John's.
M.B., B.C.—S. G. Platts, Caius.

Victoria University of Manchester.—At examinations held recently the following candidates were successful in the subjects indicated:—

Final M.B. and Ch.B.

W. S. Booth, Clara A. Lomas (First Class Honours; distinction in Obstetrics, Surgery, and Medicine), J. G. McKinlay, Kamil Maximus, H. A. Sandiford (awarded distinction in Surgery), Henry Wilson, and S. A. Winstanley.

Medicine.—S. G. J. Dowling.

Forensic Medicine and Toxicology.—Robert Chevassut, J. S. Chorlton, S. G. J. Dowling, Joseph Fielding, G. B. Horrocks, J. D. Kenyon (awarded distinction), and H. H. Stones.

Third M.B. and Ch.B. Examination.

General Pathology and Morbid Anatomy.—J. H. Albinson, Hitchon Chadwick, William Christopher, Richard Colley, E. W. Fish, Eva L. Glasier, Alice M. A. Holt, R. L. Newell, F. C. Ormerod, Nesta H. Perry, Dorothy Potts, C. R. Sandiford, Walter Stansfield, and G. B. Wild.

Pharmacology and Therapeutics.—J. D. Byrd, E. W. Fish, E. R. Gilmore, J. B. Leigh, B. L. Lloyd, Brian Walley, and G. B. Wild.

Hygiene.—J. H. Albinson, E. W. Fish, E. R. Gilmore, J. B. Leigh, B. L. Lloyd, Brian Walley, and G. B. Wild.

Second M.B. and Ch.B. Examination.

F. H. Anderson (awarded distinction in Anatomy), G. E. Archer, Mercy D. Barber, W. T. G. Boul, Hilda K. Brade, C. F. J. Carruthers, Kathleen L. Cass, Ruth E. Conway, J. C. T. Fiddes, Jacob Holker, Norman Kletz, E. N. P. Martland, A. B. Platt, Elizabeth C. Powell, Jacob Shlosberg, D. M. Sutherland, Harry Taylor, and Henry Tomlinson.

Physiology.—A. M. Cotes and R. S. Paterson.

University of Leeds.—At a Congregation held at the School of Medicine on Dec. 19th the following medical degrees were conferred:—

M.B., Ch.B—W. D. Anderton, S. N. Cohen, T. Elliott, H. Foxton, C. M. Gozney, A. S. Hebblethwaite (second-class honours), E. Hesterlow, F. King, J. J. Digges La Touche, H. W. Robinson, J. Wilkinson (with second-class honours), and J. Wright.

The following pass-lists are posted:—

Final Examination for M.B., Ch.B.

Part I., Pathology and Bacteriology.—Z. P. Fernandez, Miriam Hutchinson, and C. R. Knowles.

Part II., Forensic Medicine and Public Health.—H. Foxton, F. King, J. J. Digges La Touche, and C. H. Seville.

Second Examination for M.B., Ch.B.

Part I., Anatomy and Physiology.—S. Adler, G. R. Baxter, H. E. Charles, H. V. Horsfall, G. F. Hurst, J. H. Parker, N. Pick, C. Riley-Watson, W. H. Rowden, P. Shillito, and C. H. Smith.

Part II., Pharmacy.—G. R. Baxter, A. P. Bertwistle, Marion Draper, H. Goodman, J. Gordon, K. Jaidka, and F. H. Smith.

First Examination for the Degree of Bachelor of Dental Surgery

Part III., Dental Mechanics and Dental Metallurgy.—L. Waring.

Final Examination for the L.D.S.

Part I.—A. L. Fraser.
Part II.—N. T. Williamson.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held recently the following gentlemen, having passed the requisite examinations between Oct. 5th and 8th, were admitted Fellows (F.R.C.S. Edin.):—

George Joseph Adams, M.B., Ch.B. Edin., Edinburgh; Howard Greene Barrie, M.R.C.S. Eng., L.R.C.P. Lond., Kuling, China; Francis James Browne, M.B., Ch.B. Aberd., Abertillery, Mon.; Herbert Ernest Clutterbuck, M.D., C.M. Toronto, Toronto, Canada; Premananda Das, L.M.S. Calcutta, L.R.C.S. Edin., Calcutta, India; John Flynne, L.R.C.S.E. (Triple), Ipswich, Queensland; Arthur Jonas Friedlander, M.R.C.S. Eng., L.R.C.P. Lond., Essex; Henry Edwardes Griffiths, M.R.C.S. Eng. L.R.C.P. Lond., Grahamstown, South Africa; John Kirk, M.B., Ch.B. Edin., Canton, South China; Leonard Hugh McBride, M.D. New Zealand, London; Percy Peter James Stewart, M.B., Ch.B. New Zealand, Dunedin, Otago, New Zealand; William George Thompson, M.D. Edin., Sunderland; and Thomas Jefferson Williams, M.D. Iowa, L.R.C.S. Edin., Chicago, Illinois, U.S.A.

University of Durham: Faculty of Medicine.—At the Convocation held on Dec. 15th the following degrees were conferred:—

Bachelor of Medicine (M.B.).—Arthur Causton Freeth, St. Mary's Hospital; Grace Winifred Pailthorpe, London School of Medicine for Women; Ernest Charles Gilchrist Parker, College of Medicine, Newcastle-upon-Tyne; Home Playfair-Robertson, St. Bartholomew's Hospital; and Sarah Louisa Rook, College of Medicine, Newcastle-upon-Tyne.

Bachelor of Surgery (B.S.).—John Bain Alderson, M.B., College of Medicine, Newcastle-upon-Tyne; Grace Winifred Pailthorpe, London School of Medicine for Women; and Sarah Louisa Rook, College of Medicine, Newcastle-upon-Tyne.

We regret to announce the death, on Dec. 22nd, of Sir Robert Simon, who recently resigned from the post of physician to the Birmingham General Hospital, after 35 years' service upon the honorary medical staff of that institution.

Oxford Ophthalmological Congress.—This Congress will assemble at Keble College, Oxford, on the evening of Wednesday, July 14th, 1915, and the meeting will be held on the two following days. A discussion will take place upon Industrial Diseases and Accidents, to be opened by Dr. Frank Shufflebotham. The subject of Coal-miner's Nystagmus will be discussed by Dr. T. Harrison Butler, Mr. T. S. Maitland, Mr. J. Jameson Evans, and Dr. A. C. Norman. Industrial Cataract will be dealt with by Dr. William Robinson; Plumbism as it Affects the Eye, by Mr. S. McMurray; Steel Furnace Accidents, by Mr. S. H. Pooley; and Some of the Rarer Industrial Diseases of the Eye, by Mr. Sydney Stephenson, Master of the Congress. Dr. J. Gray Clegg and Dr. E. L. Collis will also contribute papers. The first day of the meeting will be devoted to demonstrations, and members are asked to assist with cases, specimens, operations, or novelties. The honorary secretary is Mr. Bernard Cridland, of Wolverhampton.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALEXANDER, W. H. M., M.B., C.M. Glasg., has been appointed Medical Officer of Health to the Crowle Urban District Council.

BUSHNELL, FRANK GEORGE, M.D., B.S. Lond., L.R C.P. Lond., M.R.C.S., D.P.H. Camb., has been appointed Tuberculosis Officer to the Plymouth Borough Council.

HALL, OCTAVIUS, L.R.C.P. & S. Edin., L.F.P.S. Glasg., D.P.H. Irel., has been appointed Medical Officer of Health of Plymouth.

MACPHERSON, R. W., M.D. Aberd., has been appointed Assistant School Medical Officer for the County of Cheshire.

MAGEE, J. R., L.R.C.P. & S. Irel., has been appointed Medical Officer to the Londonderry Port Sanitary Authority.

MARSDEN, J. ASPINALL, M.R.C.S., L.S.A., has been appointed Medical Officer of Health to the Hipperholm Urban District Council.

MARTIN, DOUGLAS, M.B., Ch.B. Edin., D.T.M., has been appointed Assistant School Medical Officer and Assistant Medical Officer of Health for the County Borough of South Shields.

MURRAY, SYDNEY E., L.M.S.S.A., has been appointed School Medical Officer to the Sutherland Town Council.

WILLIAMS, FREDERICK MANN, M.R.C.S., L.R.C.P. Edin., D.P.H. Camb., has been appointed Consulting Medical Officer of Health of Plymouth.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (*see Index*).

BARNSLEY, BECKETT HOSPITAL AND DISPENSARY.—Second House Surgeon, unmarried. Salary £100 per annum, with apartments, board, and laundry.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.

BEDFORD COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and laundry.

BIRKENHEAD BOROUGH HOSPITAL.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

BIRMINGHAM CITY MENTAL HOSPITAL, Rubery-hill.—Female Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street.—Senior and Junior House Surgeons. Salaries £110 and £100 per annum respectively, with residence and board, &c.

BIRMINGHAM UNION.—DUDLEY-ROAD INFIRMARY: Second Assistant Medical Officer. Salary at rate of £210 per annum. Third Assistant Medical Officer. Salary at rate of £170 per annum. Fourth Assistant Medical Officer. Salary at rate of £160 per annum. SELLY OAK INFIRMARY: Assistant Medical Officer. Salary at rate of £180 per annum. All with apartments, rations, laundry, and attendance.

BIRMINGHAM, YARDLEY-ROAD SANATORIUM AND ANTI-TUBERCULOSIS CENTRE.—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.

BRADFORD ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

BRADFORD, ST. LUKE'S HOSPITAL AND UNION HOUSE.—Assistant Resident Medical Officer, unmarried. Salary £150 per annum, with rations, apartments, and washing.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried. Salary at rate of £125 per annum, with board, lodging, and washing.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN.—House Surgeon. Salary at rate of £100 per annum, with board, lodging, and washing.

BURLEY-IN-WHARFEDALE, SCALEBOR PARK ASYLUM.—Assistant Medical Officer. Salary £250 per annum, with rooms, board, attendance, and washing. Or Locum Tenens for winter months. Salary £5 5s. per week.

CANCER HOSPITAL, Fulham-road, S.W.—Surgical Registrar. Salary £100 per annum.

CANTERBURY, KENT COUNTY ASYLUM, Chartham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—Two House Surgeons for six months. Salary at rate of £140 per annum each, with board, residence, and laundry.

CARLISLE, CUMBERLAND AND WESTMORLAND ASYLUM, Garlands.—Junior Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, and washing.

CHESTER, CITY AND COUNTY OF THE CITY OF.—Assistant Medical Officer of Health. Salary £300 per annum.

CHICHESTER, WEST SUSSEX COUNTY MENTAL HOSPITAL.—Second Assistant Medical Officer Salary £250 per annum, with apartments, board, laundry, and attendance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Physician to Out-patients.

CITY OF LONDON UNION INSTITUTION AND INFIRMARY, 42, Clifton-road, Lower Clapton, N.E.—Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, rations, and washing.

CITY OF WESTMINSTER UNION INFIRMARY, Fulham-road, S.W.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salaries £160 and £140 per annum respectively, with board, residence, and washing.

CROYDON GENERAL HOSPITAL.—Senior House Surgeon. Salary £105 per annum, with residence, board, and laundry.

DOUGLAS, ISLE OF MAN, NOBLE'S HOSPITAL.—Resident House Surgeon, unmarried. Salary £150 per annum, with board and laundry.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £100 per annum, with board, residence, and washing.

EDINBURGH UNIVERSITY.—Lectureship on Chemical Physiology. Salary £300 per annum.

EDMONTON EDUCATION COMMITTEE, URBAN DISTRICT COUNCIL, Middlesex.—Temporary Assistant School Medical Officer and Certifying Officer. Salary at rate of £300 per annum.

EDMONTON UNION INFIRMARY, 77, Bridport-road, Upper Edmonton.—Second Assistant Medical Officer, unmarried. Salary £160 per annum, with residential allowance.

GLOUCESTER, GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £200 per annum, with board, lodging, and washing.

HULL CITY ASYLUM.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

JHARIA MINING SETTLEMENT, Bihar, India.—Chief Sanitary Officer. Salary Rs. 1200 (£80), rising to Rs. 1500 (£100) a month, with house.

LEEDS GENERAL INFIRMARY.—Ophthalmic House Surgeon for six months. Salary £50 per annum, with board, residence, and laundry.

LEICESTER ROYAL INFIRMARY.—Ophthalmic House Surgeon and Assistant House Physician (joint post). Also Two Assistant House Surgeons. Salaries at rate of £100 per annum, with board, apartments, washing, and bonus. Also Two Assistant Resident Medical Officers for six months, with board and apartments.

LERWICK PARISH COUNCIL AND SHETLAND COMBINATION POORHOUSE COMMITTEE.—Medical Officer. Salary £78 per annum.

LIVERPOOL, BROWNLOW-HILL INSTITUTION.—Resident Assistant Medical Officers. Salary £250 per annum, with apartments and usual resident allowances.

LOWESTOFT AND NORTH SUFFOLK HOSPITAL.—House Surgeon, unmarried. Salary at rate of £150 per annum, with board, residence, and laundry.

MAIDSTONE, KENT COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £250 per annum, with board, quarters, attendance, washing, &c.

MANCHESTER, COUNTY ASYLUM, Prestwich.—Locum Tenens, unmarried. Salary £5 5s. per week.

MANCHESTER EDUCATION COMMITTEE.—Female Assistant School Medical Officer, unmarried. Salary £300 per annum.

MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.

MANCHESTER ROYAL EYE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior House Surgeon for six months. Salary £100 per annum, with board, residence, and laundry.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.—Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and washing.

NEWCASTLE-UPON-TYNE CITY HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Assistant. Salary £250 per annum, with board, lodging, &c.

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE.—Assistant School Medical Officers (One Male and One Female). Salaries £300 per annum.

NEWCASTLE-UPON-TYNE AND NORTHUMBERLAND SANATORIUM FOR CONSUMPTIVES, Barrasford, North Tyne.—Resident Medical Officer. Salary £350 per annum, with board, residence, and laundry.

NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry. Also Honorary Medical Officer to Ear, Nose, and Throat Department.

Notes, Short Comments, and Answers to Correspondents.

THE SYSTEMATIC PHYSICAL EXAMINATION OF INDUSTRIAL WORKERS.

THE importance of systematic physical examination of workers is well emphasised in a paper read before the Session on Industrial Hygiene at the Third Annual Congress of the National Council for Industrial Safety, Chicago, last October, by Surgeon J. W. Schereschewsky, of the United States Public Health Service.[1] Valuable as such a procedure is for safeguarding the health of the individual worker in industrial concerns, Dr. Schereschewsky emphasises its great importance to the progress of the science of industrial hygiene. The general introduction of systems of medical supervision, he says, with periodic physical examinations in various industries will result in the collection of a body of data similar to those already obtained in New York by the careful physical examination of several thousand garment workers, which when studied will form a logical basis for practical recommendations to make all such industries safe from a health standpoint. Each industry thus treated will be enabled to see to its own sanitation, with the result that the enormous economic loss caused in industries by preventible diseases and disabilities will disappear.

OFFICIAL MANNERS.

To the Editor of THE LANCET.

SIR,—The note in your issue of Dec. 12th under the above title interested me much. I was recently a candidate for a post under the H —— County Council—applications to be sent in by Oct. 6th—but up to date I have not received even a printed postcard acknowledging my candidature! In fact, had my chief not told me that he had received a "confidential" letter from the medical officer of health concerned, inquiring as to my credentials, I should have been in doubt as to whether my application had not gone astray in the post. I enclose my card. I am, Sir, yours faithfully,

I.M.S.

HEALTH AND HOSPITALS IN TRINIDAD.

THE report on the Blue Book of Trinidad and Tobago for the year 1913–14 has just been presented to Parliament. It states that the health of the colony during the year was good, but that an unfortunate outbreak of yellow fever occurred at the Brighton oilfields, where there were 10 cases and 3 deaths. The prompt action of the sanitary authorities kept the outbreak in check and it did not spread to any other district. The estimated population on March 31st, 1914, was 352,145—an increase of 6748. The number of births during 1913–14 was 11,825, and the number of deaths 8121. A further increase of 3046 was due to immigration. The Colonial Hospital, Port of Spain, with 320 beds, is the most important in the colony. The number of patients admitted at this institution during the year was 5579, and the daily average in hospital 269. At the San Fernando Hospital, which has 120 beds, 2991 persons were admitted, the daily average in hospital being 110. District hospitals are also maintained by the Government at Tobago, Arima, St. Joseph, Tacarigua, Couva, Princes Town, and Cedros, with an aggregate accommodation of 246 beds. There are two hospitals devoted entirely to the treatment of persons suffering from yaws—one in Trinidad and the other in Tobago. The former has accommodation for 200 patients and the latter for 160. The use of salvarsan is still continued with favourable results in the treatment of this disease, but the number of patients has again increased, there being at the present time 72 cases under treatment in Trinidad and 57 in Tobago.

Dr. N. Mayne.—It would have been better to make sure that the case contained instruments and that the practitioner intended to operate without consulting the surgeon to the infirmary. The operation in question is very usually performed in collaboration.

Nemo.—The medical referee's behaviour was not correct and cannot be defended.

W. W. S (Genoa).—Our correspondent is too ferocious.

F. W.—Warwick and Tunstall's "First Aid to the Sick and Wounded" (Bristol: John Wright and Sons, Limited. Price 1*s*.; leather, 2*s*. 6*d*.) contains an admirable and fairly detailed (60 pages) and well illustrated epitome of anatomy and physiology, which should be amply sufficient for the nurse's requirements and meet the necessities of a nurse's examination. A "Text-book of Anatomy and Physiology for Nurses," also, by Amy E. Pope (New York: G. P. Putnam's Sons. 1913. Price 6s.) was reviewed in THE LANCET, Jan. 10th, 1914, p. 111.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page for the current half year are published in this issue, which completes the second volume of the year 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

"LESLIES' ZINCOPLAST"

A MUCH IMPROVED MAKE OF ZINC OXIDE PLASTER. STRONGLY SELF-ADHESIVE; NON-IRRITATING; DOES NOT DRY UP.

May be obtained on White or Pink Tinted Cloth, 5 yd. or 10 yd. spools, in all the usual widths.

Medical Officers and Pharmacists are invited to write for Trial Sample.

SURGEON'S CASE

THE NEATEST AND MOST COMPACT ON THE MARKET.

Containing 1 each ½, ¾, 1, and 2 in. Spools of ZINCOPLAST on White or Pink Tinted Cotton Cloth.

Or may be had filled with Rubber Adhesive Plaster on White Cloth. Refills can always be obtained.

ORDER ONE ON APPROVAL FROM YOUR WHOLESALE HOUSE.

LESLIES, Ltd., 18, Eldon Street, London, E.C.

BULLOCK'S PEPSINA PORCI.

DOSE—2 to 4 GRAINS.

ACID GLYCERINE OF PEPSINE

DOSE 1 to 2 DRMS. (BULLOCK).

In this preparation advantage has been taken of the solubility of Pepsine in Glycerine to produce a convenient and desirable *liquid form* of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsin the property of keeping for any length of time.

May be prescribed with most substances compatible with Acids.
In 4-oz., 8-oz., and 16-oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A. Cantab., F.C.S., F.L.S., &c., Dr. PAVY, Professor TUSON, the late Professor GARROD, Dr. ARNOLD LEES, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

J. L. BULLOCK & CO., 3, Hanover St., Hanover Sq., London, W.

GOLD MEDAL, INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps, the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ CO. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water.

MEDICAL OPINIONS.

"I have tried your Mist. Damianæ Co. considerably in the dyspepsia of commencing phthisis, and can very strongly recommend its use in those cases. It soothes the stomach wonderfully, and enables the patient to take more food whilst acting as a powerful stimulant in relieving exhaustion."—Yours faithfully, W. H. B——, B.A. (Cantab.), M.R.C.S., L.S.A.

THE MEDICAL ANNUAL.—"Damianæ is not used so frequently in this country as in America, where its value as a tonic for Neurasthenia is well known. Messrs. HEWLETT & SON put up a very excellent preparation of this drug, combined with Nux Vomica and simple aromatics and bitters, which is valuable for dispensing, and yields very satisfactory results in treatment."—1898.

Dr. M——, R.N., writes:— "Farnham (Hants.), Sept. 1903.
"I have frequently prescribed your Mist. Damianæ Co. and proved it efficient in treating Neurasthenia."

PRICE 11/- per lb. Packed in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Introduced and Prepared only by—

C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte St., LONDON, E.C.

THE TERRITORIAL MEDICAL SERVICE

By a Special Correspondent of THE LANCET.

With Preface by Sir ALFRED H. KEOGH, K.C.B., Director-General, Army Medical Service.

REPRINTED FROM THE LANCET, July 31st, &c., 1909.

The Subjects dealt with include: Organization Duties in Camp—Selection of Sites for Camps—Selection of Water Supplies for Camps: Filters—Sanitary Upkeep of Camps: Latrines; Urinals; Cooking-places; Refuse Disposal—Medical Examination of Recruits: Diseases of the Heart; Teeth; Varicocele; Flat Feet; Syphilis—Selection of Men for Active Service; Age; Previous Medical History and its Bearing; Physical Examination—Some Medical Aspects of Marching—Medical Aspect of the Food Supply of the Soldier.

An Army Medical Officer writes:—

"I have read with the greatest interest your pamphlet, 'The Territorial Medical Service.' It bristles with information, and I think every medical man, whether connected with the Territorial Force or not, should obtain a copy. It would help him in various ways, and prevent him making mistakes."

THE LANCET Offices, 423 & 424, Strand, W.C.; and 1 & 2, Bedford-street, adjoining.

JUST ISSUED

Allen's Local Anæsthesia

JUST ISSUED

This is a complete work on local and regional anæsthesia. It includes history and evolution, principles, physiology, toxicology, and technique; a chapter on nerves and sensation, giving particular attention to *pain*—what it is and its psychic control, and a chapter on osmosis and diffusion. Each local anæsthetic is taken up in detail, giving very special attention to *cocain* and *novocain*, pointing out their action on the nervous system, the value of adrenalin, paralysis caused by cocain anæsthesia, control of toxicity. Crile's method of administering adrenalin and salt solution, the exact way to produce the intradermal wheal, to pinch the flesh for the insertion of the needle—all are *shown* step by step. It describes Crile's *anoci-association*; anæsthesia by quinin and urea, and by the magnesium salts, spinal and epidural analgesia, paravertebral, parasacral, intra-arterial, intravenous, and general anæsthesia with local anæsthetics. The production of local anæsthesia in the various regions is taken up in detail. Abdominal work covers 50 pages, genito-urinary work and hernia another 50 pages. Local anæsthesia for rectal surgery, gynæcological operations, and Cæsarean section; for head and skull work, for eye, ear, nose and throat work, and a large section on *dental anæsthesia*, are included.

Octavo of 625 pages, 255 illustrations. By CARROLL W. ALLEN, M.D., Instructor in Clinical Surgery at Tulane University of Louisiana. With an Introduction by RUDOLPH MATAS, M.D. Cloth, 25s. net.

SAUNDERS

Garrison's History of Medicine

Dr. Garrison's new work gives a complete history of medicine from the earliest primitive times on through Egyptian, Sumerian, Oriental and Greek medicine, the Byzantine, Mohammedan, Jewish and Mediæval periods, the Renaissance, the Reformation, the seventeenth century (the age of individual scientific endeavour), the eighteenth century (the age of theories and systems), the nineteenth century (the beginning of organised advancement of science), the twentieth century (the beginning of organised preventive medicine). There are also appendices covering medical chronology (data on important diseases, drugs, therapeutic measures and surgical operations) and bibliographic notes for collateral reading. The illustrations, many of which are portraits, are extremely interesting and instructive.

"*The best general history of medicine at present to be found in the English tongue.*"—THE LANCET.

Octavo of 763 pages, with many illustrations. By FIELDING H. GARRISON, M.D., Principal Assistant Librarian, Surgeon-General's Office, Washington, D. C., and Editor of the *Index Medicus*. Cloth, 25s. net.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith & Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

NOW READY. THIRD EDITION. Crown 8vo. Revised and Enlarged. 5/- net.

THE NEWER PHYSIOLOGY
IN SURGICAL AND GENERAL PRACTICE.

By A. RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng.

Hunterian Professor R.C.S.; Hon. Assistant Surgeon, Bristol Royal Infirmary; Senior Demonstrator of Physiology, University of Bristol.

Gathers out from the newest developments of Physiology what is of most value in Treatment in a form which may be of assistance to the general practitioner, surgeon, and candidates for examination in physiology.

"Contains much useful information based upon recent physiology, which the reader, be he physician or surgeon, will find of value in the diagnosis of disease and treatment of the sick."—*Brit. Med. Jour.*

FOURTH EDITION. Revised and Illustrated. Crown 8vo. 9/6 net.

SYNOPSIS OF SURGERY.

For STUDENTS and PRACTITIONERS.

By ERNEST W. HEY GROVES, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng.

Surgeon, Bristol General Hospital; Lecturer in Surgery, Bristol University.

"It appears to contain all that is necessary in a synopsis, and the phraseology is not too condensed. Such a book as this may be legitimately employed for revising knowledge."—*Lancet.*

"The facts which present the best and most modern surgical teaching have been so well arranged by Mr. Groves that the reader will not only find what he wants with ease, but will also be enabled to follow the subject of his reference with interest and profit. . . . May be regarded as complete in its range of subjects. . . . The additions necessary to keep it quite up to date have been freely made. . . . Among the best of its kind, and the author is to be congratulated on its readableness, its lucidity, and its fulness—notable qualities."—*Brit. Med. Jour.*

BRISTOL: JOHN WRIGHT & SONS LTD. LONDON: SIMPKIN & CO. LTD.

By Sir LAUDER BRUNTON, Bt., M.D., F.R.C.P., F.R.S., &c.

SECOND EDITION. ALMOST ENTIRELY REWRITTEN.

THERAPEUTICS OF THE CIRCULATION

Small Foolscap 8vo. With 111 Illustrations. Price 5s. net.

"There can be few British medical men who are unacquainted with the author's lucid style and practical method of exposition. In this book they will find a sound and up-to-date account of the subject dealt with, and full descriptions of the various therapeutic measures employed in the relief of the symptoms of cardio-vascular disease. It may be cordially recommended to students and practitioners of medicine."—THE LANCET.

"The subject is dealt with by a master-hand."—THE PRESCRIBER.

167-173, GRAY'S INN ROAD, LONDON, W.C.

Where Lecithin is indicated—

IF it be desired to administer the organic glycerophosphates of Lecithin-Ovo in solution, the most palatable and efficient medium is Junora wine. Junora may be prescribed with advantage for malnutrition, anæmia and debility, during convalescence and in other cases where Lecithin is indicated. It is an alcoholic beverage (about the same strength as Burgundy) because alcohol is the only practicable solvent for Lecithin. Junora creates appetite, increases the activity of the blood-forming organs, strengthens the nervous system and improves the whole nutritive condition.

JUNORA is supplied in two strengths :—		Per bottle.
A. About ¾-gr. Lecithin-Ovo products to the oz.	...	2/11
B. About 5-grs. Lecithin-Ovo products to the oz.	...	4/-

SPECIAL TERMS TO MEDICAL MEN

A full-sized trial bottle of Junora will be sent free to any Doctor on Application.

Humphrey Taylor & Co.

By Appointment to H.M. The King.

JUNORA

WINE OF HEALTH

Proprietors: Messrs. HUMPHREY TAYLOR & CO., Ltd.
(Established 1770)
45, NEW OXFORD STREET, LONDON, W.C.

By Appointment to H.M. The King.

THE Lecithin-Ovo made by Messrs. Humphrey Taylor & Co. is the finest Lecithin obtainable. It is made exclusively in England, and is of uniform purity and efficiency. Every process of its manufacture has been examined and tested by the leading authorities on Lecithin in Great Britain, and their considered opinion is that Lecithin-Ovo thus obtained is superior in quality to any foreign preparation of Lecithin.

Lecithin-Ovo

40/- per lb. **3/6** per oz.

Lecithin-Ovo Capsules	1½ grs., **4/6** per 100. 3 grs., **8/6** per 100.
Lecithin-Ovo Powders	Finest quality from 10 to 30 per cent. strength at lowest prices.

Samples and quotations sent free on application to the Proprietors, who invite comparison of their quality and prices.

In DIABETES, GOUT, RHEUMATISM, &c.,

"G.B." Diabetes Whisky

(Late Proprietors: GEO. BACK & Co., LTD.)

PURE MALT. SUGAR FREE.

"THE LANCET," *October 5th, 1889.*

"G.B." DIABETES WHISKY.—This Whisky is almost absolutely free from extractive matter. It yielded in our analysis only 0·0275 per cent. of solid extract and 0·005 of ash. The alcohol amounted to 44·65 per cent. in weight, equal to 91·60 of proof spirit. It has scarcely any colour, and certainly deserves its name.—(Page 701.)

5/- per bottle, 55/- per dozen, carriage paid.
GUARANTEED TEN YEARS OLD.

Samples and analyses will be sent on application to the Proprietors.

HUMPHREY TAYLOR & CO., Ltd. (Est. 1770) Bloomsbury Distillery, London, W.C.

GASTRO-INTESTINAL SYMPTOMS

BOVININE
IN
INFLUENZA

The present wave of Influenza is marked by severe Gastro-intestinal symptoms requiring careful dietetic treatment. In " Bovinine " will be found a highly nutritious preparation, easy of digestion and assimilation, invaluable in allaying irritation, in supporting the system, and in promoting convalescence. It should be given freely until strength is fully restored.

In the graver complications of Influenza, such as **Bronchitis, Pneumonia**, and **Pleurisy**, its stimulating properties are most emphasised. "Bovinine" is readily retained when all other food is rejected.

In all conditions complete reliance may be placed in " Bovinine."

On Sale at all Chemists at 1s., 2s. 9d., and 4s. 6d. per bottle. Literature, Sample, and one of our new Glass Tongue Depressors free on application to

Lysol

of all manufactures

completely Superseded by an ALL-BRITISH Antiseptic certified of Higher Disinfecting Value

TOXOL

Manufactured by Boots Pure Drug Co., Ltd.

Responding to the desire of the Medical Profession to discard preparations paying tribute to the enemies of this country, the laboratory staff of Boots, *the* Chemists (consisting of some 30 highly-trained analysts), perfected TOXOL, which is identical in all but name with "Lysol" as formerly imported from Herren Schulke & Mayr of Hamburg—a solution of cresols in a saponaceous medium—and superior in strength of disinfecting power.

TOXOL is pronounced by medical men who are using it to have all the qualities of "Lysol," and is certified on high authority to excel *all* samples of "Lysol" in disinfecting co-efficient.

Copy of Report by Dr. SAMUEL RIDEAL, joint-originator of the RIDEAL-WALKER Co-efficiency Test. November 16, 1914.

"I have purchased at one of your branches samples of TOXOL, and my results on examination confirm your labelled strength that it is two and a half times as powerful as Phenol, and it is higher than all samples of 'Lysol' I have examined." *(Signed)* SAMUEL RIDEAL.

The following are extracts from the letters of Medical Men who have already used TOXOL to replace "Lysol":—

"It seems to be in every way quite satisfactory and an excellent substitute for 'Lysol.'"

"Very glad to test and prove that English science is as good as that of the Barbarians. It would be a good thing to circularise the profession with a list of alien enemies' products."

"I tried it on a septic finger and found it all you stated it to be."

"TOXOL is very satisfactory. The medical profession ought to feel grateful to Sir Jesse Boot for replacing a German article in such a prompt and satisfactory manner."

"Am using sample and I am so pleased with it that I shall continue to use TOXOL in future."

"An excellent preparation. I obtained 'Lysol' many times from Hamburg before any English chemist would stock it, so am interested in your venture."

"Dr. —— is pleased to see an English manufacturer superseding a German product, and he will give his support to such a company as will do this."

"Many thanks; have used solutions of TOXOL in various strengths for numerous minor surgical cases with most satisfactory results."

"Will give TOXOL a trial. Am much interested in finding that your firm has succeeded in making a preparation in England of a German make like 'Lysol.' It is much more efficient than the German."

"Superior to 'Lysol' as far as I have tried it."

Samples of TOXOL will be delivered free on application to Medical Men who have not yet tested it.

TOXOL is sold in 6½d., 11d., 1s. 7d., *and* 2s. 9d. *bottles at all branches or Sent carriage paid to any Medical Man at above prices; address Boots, M. O. Nottingham.*

LETTERS TO MEDICAL MEN

THE TREATMENT OF PNEUMONIA BY PHYLACOGEN.

NOTE.—The medical reports quoted in this letter are published by permission. On request we shall be glad to place any *bonâ-fide* enquirer in communication with the authors.

Mortality from Pneumonia.

DEAR SIR,—The mortality from pneumonia is always highest in the winter months. For example, we find that the mortality in London Hospitals during the past twelve months was as follows:—October to December, 1913, 1326; January to March, 1914, 1618; April to June, 1345; July to September, 871; giving a total for the year of 5160. Owing to the year having been exceptionally mild the mortality from Pneumonia is down by about 10 per cent. as compared with the previous year, but even so it indicates, if we are to assume that the rest of the country suffers in the same proportion as London, that the annual mortality in the British Isles must reach the enormous total of at least 55,000, or more than one thousand per week. Any treatment designed to reduce this huge mortality cannot fail to invite investigation by the medical profession.

Accurate Diagnosis Essential.

The figures mentioned above do not include the thousands of cases which lie on the border line. Apparently, it should not be difficult to make a definite diagnosis of pneumonia, and to determine the presence of complications, but clinical experience prompts the suggestion that this is not accomplished as often as is presumed; that many cases are diagnosed as "plain" pneumonia, whereas they are complicated with conditions in which the use of Pneumonia Phylacogen would be fruitless. For example, in not a few cases diagnosed as "pneumonia," autopsies have disclosed tubercular meningitis, acute miliary tuberculosis, &c., while complications with uræmia, acute nephritis, puerperal sepsis, cerebral meningitis, scarlet fever, &c., are also found.

Clinical Results.

The clinical study of Pneumonia Phylacogen has been diligently carried on by our Department of Experimental Medicine during the past three years, and some hundreds of cases have been reported. The records show a number in which there was no hope or apparent possibility of recovery by the ordinary treatment, but which ultimately did recover under the use of Phylacogen. At our London office alone we have received, during the past few months, definite reports of 26 cases, 22 of which recovered, and 4 died. Of the recoveries, in several cases a fatal prognosis had been made, while in others the period of illness was reduced by at least one-half.

Sudden Fall of Temperature.

One feature in the Phylacogen treatment of pneumonia is the occasional sudden reduction of the temperature, which sometimes falls even to the sub-normal. This should cause no more alarm than a similar drop in temperature during the crisis in pneumonia occurring under other treatment. The chart on the next column gives an illustration of what is frequently found in such cases.

The following report comes from Wales, and we transcribe it exactly as received. Man, aged 28, small patch of lobar pneumonia in left axilla, most intense toxæmia, temperature 105° for three days, wild delirium for eight days. Patient was seen by a consultant, who pronounced the case hopeless. On commencing Phylacogen treatment the temperature showed a gradual but persistent fall, and in six days became normal. The doses were 1 c.c., 2 c.c., 3 c.c., 3 c.c., 4 c.c., 4 c.c. Hypodermic injections of Strychnine, 1/60 grain, and Digitalin, 1/100, were given every four hours. The patient at one time showed signs of twitching under the strychnine, but use was persisted in although in smaller doses. The patient made an excellent recovery.

Broncho-pneumonia.

The accompanying chart refers to a case of Broncho-pneumonia. F. G., age 4, admitted direct from the school-room to the hospital on December 10th, temperature 103·8°, short hurried breathing, loose offensive stools, occasional cough, complained of earache. December 11th, ½ c.c. Pneumonia Phylacogen given at 10 A.M.; 2 P.M., temperature 102°; 6 P.M., temperature 101·6°. December 12th, temperature 99·6°, good night, slept well, pulse good, no pain or tenderness at site of injection, no cough, has taken nourishment well; evening temperature 99°, very good day. December 13th, very good night, temperature 98·6°; 6 P.M., temperature 99°, good day, cough loose. December 14th, temperature 98·4°, very good night; evening temperature, 99·4°, fairly good day. December 15th, temperature 98°, good night; evening temperature 98·4°, very good day. December 16th, 17th, and 18th, morning temperature 98°; evening temperature on the 17th 98°. The patient got up on the 18th, and no further record was taken. We have a number of other reports very similar to the above, in which the temperature came down after one dose, and of other cases in which two doses were required. The Medical Superintendent of the Hospital, who furnishes these reports, informs us that in these cases past experience has been that the high temperatures ran from five to seven days before the crisis was reached.

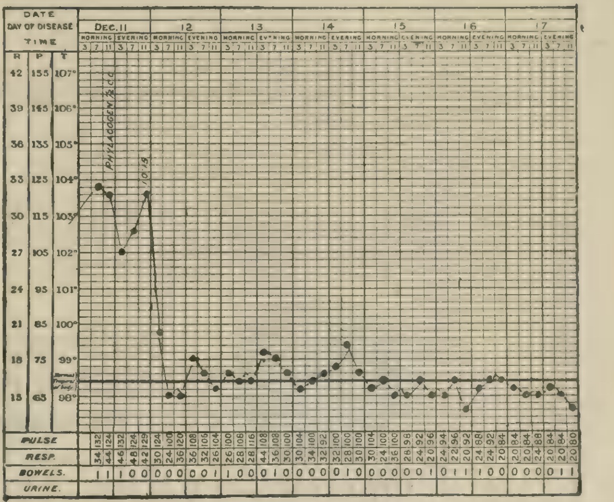

CHART OF A CASE OF BRONCHO-PNEUMONIA.

We have issued a booklet of 52 pages giving full particulars of Pneumonia Phylacogen; these contain extended case histories of 36 cases which recovered, and of 10 cases which had been treated with Phylacogen but in which death occurred. A copy of this booklet will be sent to any medical man on request.

Yours respectfully,

PARKE, DAVIS & Co.

Beak Street, Regent Street, London, W.

Vitafer

The Premier TONIC FOOD.

VITAFER is no hastily concocted preparation to meet the war demand for goods of British origin. Some of these are practically only dried skim milk powder with glycerophosphate, and are only of about half the real nerve nutritive value of such a preparation, as VITAFER, and, what is of serious moment to Diabetic patients, contain the whole of the milk sugar from which VITAFER is carefully freed.

To illustrate this point, we submit side by side the analysis of VITAFER and of one of the newest of these numerous claimants.

	VITAFER	THE TYPICAL EXAMPLE
Nitrogen	10.30	4.98
Chemically pure proteins	68.40	31.40
Sugar	absent	42.31

Comment is surely needless !

VITAFER contains certain substances essential to nutrition, known as Vitamines. In the case of Foods in which Ether is used for extraction, they are deprived of these valuable properties.

GOLD MEDAL awarded to VITAFER at the International Congress of Medicine, London.

VITAFER is sold at prices which bring it within the reach of all classes. — 2 oz. Tins, 1/3 4 oz. 2/- 8 oz. 3/6 16 oz. 6/-

Samples and full particulars post free to the Medical Profession, address—

Sole Proprietors and Manufacturers:
SOUTHALL BROS. & BARCLAY, Ltd., BIRMINGHAM.

Vitafer Chocolate

In Tablets containing 10 per cent. of Vitafer.

A delicious confection and a genuine stimulant.

Specially intended for travellers, sportsmen, and busy men and women who require a pick-me-up between irregular meals.

It is also ideal for Soldiers at the front, on the march, in training, etc.

In 6d. and 1/- packets of 12 and 24 tablets.

Rheumatism—Gout—Lithiasis—
Sciatica—Eczema—and Obesity
Of special value in ARTERIO-SCLEROSIS.

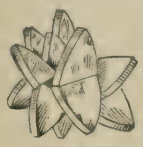
Urodonal

37 TIMES MORE POWERFUL THAN LITHIA.

Dissolves Uric Acid, Oxalic Acid, and Xantho=Uric Bodies,

Oxidises Cholesterin, Glucose, & Fats,

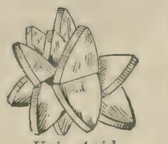
Eliminates Urea and Chlorides,
and
Restores Arterial Tension to Normal



Uric Acid Crystals.

3 teaspoonfuls per day, each teaspoonful in a glass of water, taken between meals, 10 days per month.

Acute conditions: 3 dessertspoonfuls per day. No Contra-indication, and may be continued indefinitely without any inconvenience.



Uric Acid Crystals.

GOLD MEDAL, LONDON, 1908
Grand Prix, Nancy and Quito, 1909

COMMUNICATIONS:
Academy of Medicine, Paris, 10th Nov., 1908.
Academy of Sciences, Paris, 14th Dec., 1908.

URIC ACID is never found free in the organism. It always exists in a state of combination with Soda, Ammonia, &c.; it forms biurates or quadriurates, which are complex and not easily soluble.

URODONAL by reason of its special composition, is able to effect the double chemical decompositions which liberate the Uric Acid from the combinations where it is fixed, and cause it to be easily eliminated in the urine.

URODONAL is a most powerful solvent of **URIC ACID,** because it can destroy its organic combinations.

URODONAL, JUBOL, GLOBEOL, FILUDINE,
Prepared by J. L. CHATELAIN, 2 & 2 bis, rue de Valenciennes, Paris.
Can be obtained from all Chemists and Stores, or from the London and Colonial Agents,

Samples sent free to the Medical Profession on application to Heppell & Co.

The "Allenburys" Cod-Liver Oil and its Preparations.

(Trade Mark)

"*It is as nearly tasteless as Cod-Liver Oil can be.*"—LANCET.

The "Allenburys" Cod-Liver Oil is obtained from the finest selected livers of fresh cod, and prepared at Allen & Hanburys' own factories at Lofoten and Söndmör, in Norway. It is the result of manufacturing experience of nearly half a century, and represents the highest technical skill. The process of manufacture ensures the elimination of all unpleasant and harmful products. The "Allenburys" Cod-Liver Oil is therefore perfectly pure, and by its merit alone has obtained a unique position in the estimation of the profession. It is retained and assimilated when other Cod-Liver Oils derange the digestive system, and its full nutritive power is thereby assured.

"Bynol"

(Trade Mark)

"*A perfect combination of Malt Extract and Cod-Liver Oil.*"—B.M.J.

"Bynol," the "Allenburys" Malt and Oil, presents the pure "Allenburys" Cod-Liver Oil in intimate association with the finest Malt Extract. It contains a very high percentage of Cod-Liver Oil and is a valuable nutrient and digestive. Palatable and acceptable to the most fastidious, it is readily assimilated even when the digestive organs are impaired.

"Bynin" Emulsion

(Trade Mark)

"*This preparation is doubtless a valuable one, and one which we are glad to bring before the notice of the profession.*"—LANCET.

"Bynin" Emulsion is a unique combination of the "Allenburys" Cod-Liver Oil with "Bynin" pure active liquid malt, together with the hypophosphites of lime and soda. Palatable and easily digested, it is a valuable restorative of high nutritive power. It invigorates the nervous system and nourishes the enfeebled tissues.

DESCRIPTIVE LITERATURE AND SAMPLES FREE TO MEDICAL MEN.

Niagara Falls, N.Y. Toronto. Buenos Aires. Durban. Sydney.

For Invalids, Dyspeptics and the Aged.

'Allenburys'
The DIET

Invaluable in Sickness and Convalescence.

TITLE IMPORTANT

The "Allenburys" DIET is a complete food chiefly intended for Adults, and is *quite distinct* from the "Allenburys" Foods for Infants. It is quickly prepared, exceptionally palatable, easily digested and wholly nourishing.

COMPOSITION & PREPARATION

The "Allenburys" DIET is made from pure, rich, full-cream milk and whole wheat, both ingredients being partially pancreatised during the process of manufacture. It needs boiling water only to prepare it for use.

ANALYSIS

Fat	15·4
Proteid	15·2
Soluble Carbohydrate ...	47·2
Starch	15·7
Mineral Matter	4·3
Moisture	2·2

Caloric Value of the "Allenburys" DIET when prepared ready for use:

Fat	23·8
Proteid	10·4
Carbohydrate	42·9

INDICATIONS FOR USE

In all Gastric conditions where it is found that curd is not digested, Gastritis, Gastro-Enteritis, Gastric Catarrh, Gastric Ulcer, Gastric Influenza, Obstinate Vomiting. In all Acute Disorders. Before and after Surgical Operations. In Convalescence, Gouty Dyspepsia, Insomnia, (taken last thing at night it promotes refreshing sleep and digestive rest). Neurasthenia. All forms of Tuberculosis. In Senile Disorders of the Digestion. When pure milk is not obtainable, viz., on Board Ship, in Tropical Countries or Distant Lands, or whenever a light nourishment is required. For the Invalid, Dyspeptic, and the Aged it is an essential nutrient.

ADVANTAGES

Most invalids' foods require cow's milk to be used in their preparation; this involves much time and careful mixing to avoid the presence of burnt milk or lumpiness—common characteristics of foods so prepared. The "Allenburys" DIET does not require cow's milk to be added. By the simple addition of boiling water a complete food is produced that is smooth to the palate and pleasant to the taste. The "Allenburys" DIET can be taken for prolonged periods without any distaste arising. These distinct advantages are of immense service in the work of a busy hospital or understaffed sick-room.

MANUFACTURED BY

Allen & Hanburys Ltd., Lombard St., London.

Prices: In sealed tins
1/6, 3/- and 6/- each.

'Allenburys'

BRITISH PHARMACOPŒIA, 1914

BURROUGHS WELLCOME & CO.'S products will be as hitherto

"B.P. or Better"

¶ THE BRITISH PHARMACOPŒIA, 1914, will become official on December 31, 1914. As the new Pharmacopœia will conform more closely to the advanced standards (notably in the case of melting points) adopted in the past by Burroughs Wellcome & Co., the changes, other than those of nomenclature and strength, are few so far as B. W. & Co. products are concerned.

¶ In the light of further researches, improvements will be introduced, so that all products prepared and issued by Burroughs Wellcome & Co. will, as heretofore, be B.P. or Better.

Burroughs Wellcome & Co

"MALTINE" WITH CASCARA SAGRADA

Combines certain readily appreciated Advantages:—

It is an absolutely Palatable method of prescribing Rhamnus Purshiana.

Its use is attended by no inconvenience or pain.

By means of careful selection and proper maturing of the bark, the griping principles of Cascara Sagrada are eliminated, and "MALTINE" WITH CASCARA SAGRADA has an easy, painless action.

The therapeutic action of "MALTINE" WITH CASCARA SAGRADA has been demonstrated by clinical experience, the aid afforded by "MALTINE" to the nutritive and digestive processes serving to counteract any tendency of the drug to weaken and exhaust the system.

Each fluid ounce of "MALTINE" WITH CASCARA SAGRADA contains the Liquid Extract obtained from 60 grains of the bark, the equivalent of 66 minims B.P. Liquid Extract, or about 8 grains of the dry extract.

DOSE: From a teaspoonful to a tablespoonful.

THE MALTINE MANUFACTURING COMPANY, Limited,
183, ACTON VALE, LONDON, W.,
Will be pleased to send Specimens Free of Charge to Medical Men.

In ordering, kindly specify "**MALTINE COMPANY.**"

Carnrick's Liquid Peptonoids

Contains the essential nutriment—Protein and Carbohydrates—derived from our principal foodstuffs—Beef, Wheat, and Milk. Its protein content is present in the form of peptones and albumoses obtained by physiological processes, and its entire nutritive content is immediately assimilable and available for nutrition. "LIQUID PEPTONOIDS" is Aseptic, slightly Stimulating, and eminently **Palatable**, and is readily tolerated by the sensitive and fastidious patient. The fact of its easy assimilability is the basis of its successful use in the dietetic treatment of the numerous types of cases in which it is indicated.

Regarding "LIQUID PEPTONOIDS"

The Lancet writes: "A very valuable food. . . . a very powerful and agreeable tonic and stimulant."

CARNRICK & CO., Limited, 183, Acton Vale, London, W.,

TEXTURÆ ANTIQUÆ, 88—EGYPTIAN

The Purpose of Ergot

is to produce certain physiological effects, in particular, contraction of the uterus. Research has shown that these effects are caused by definite active principles.

From
Empiricism
to Scientific
Precision

Why not use those active principles alone, omitting the unnecessary constituents of the drug?

BURROUGHS WELLCOME & CO. isolate the essentials of Ergot and issue them in a high state of purity, and of standard strength, under the title—

'ERNUTIN'

(TRADE MARK)

('Ernutin' presents Ergotoxine, 'Tyramine' and 'Ergamine')

In post-partum hæmorrhage the superiority of 'ERNUTIN' over ergot is specially marked.

After normal confinements, 'ERNUTIN' prevents or arrests hæmorrhage, promptly induces firm contraction of the uterus, improves the tone of the uterine muscle and assists involution.

'ERNUTIN' never varies in activity.

'ERNUTIN' Brand PRODUCTS

'ERNUTIN' (Oral), in bottles of 1 fl. oz., 4 fl. oz., 16 fl. oz. and 30 c.c.

'VAPOROLE' 'ERNUTIN,' sterile, in hermetically-sealed containers of min. 10 and 0·6 c.c., in boxes of 6; also 0·6 c.c. in boxes of 2

The BRITISH MEDICAL JOURNAL says:
"Time and use have justified the claims put forward for these preparations."

BENGER'S FOOD—

Describing how and why it is different to all others.

BENGER'S FOOD is a specially prepared wheaten food with which is combined two active natural digestive principles (enzymes), viz., Amylopsin and Trypsin. It is devised to be used in conjunction with fresh cow's milk, which it enriches and partially digests (more or less as desired) before consumption.

ITS ADVANTAGES. It provides a freshly prepared and delicious food cream, entirely free from irritant particles, of delicate biscuit flavour, and incapable of forming heavy curd when in contact with the acid contents of the stomach. While it is a most easily assimilated food, it is most nourishing.

ITS USES. It is relied upon in stomach and intestinal complaints and infectious diseases, and, as a supplementary food, it is especially valuable in minor ailments and mal-nutrition. For nursing mothers, it is very valuable, and is most successful as a transfer food at weaning.

BENGER'S Food *for* INFANTS, INVALIDS, AND THE AGED,
is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

TO THE MEDICAL PROFESSION OF GREAT BRITAIN.

Dear Sirs:—

A pharmaceutical remedy, which has been successfully used by the members of the medical profession for nearly 50 years with unvarying satisfactory therapeutic results, will, we believe, command your esteemed consideration. Such a remedy is HAYDEN'S VIBURNUM COMPOUND.

H. Marion Sims, of international reputation, held this product in high regard and referred to it in his text books in no unmistakable terms as to its therapeutic efficiency in gynecological conditions.

In Dysmenorrhea, Amenorrhea, Menorrhagia, Metrorrhagia, Rigid Os, Threatened Abortion and Postpartum Hemorrhages, the administration of HAYDEN'S VIBURNUM COMPOUND in teaspoonful doses given in hot water, will afford prompt relief to your patients.

HAYDEN'S VIBURNUM COMPOUND is a product of known composition and, so that you may conclusively and convincingly prove to your own satisfaction the therapeutic advantages of this original product, a card addressed to our British Agents, Messrs. Thomas Christy & Co., 4-12, Old Swan Lane, London, E. C., England, will place you in possession of a sample with ample literature. Write for it.

CONDY'S FLUID

The Pioneer Oxidant,

"AT THE FRONT"

LOTION. GARGLE. INJECTION.

Condy's Fluid purifies and cleanses the foulest wounds, immediately establishing odourless aseptic conditions without causing irritation. Unlike Condy's Fluid, Hydrogen Peroxide, the other oxidant, is very painful as a dressing, owing to the acid added to it as a preservative.

PROPER DIRECTIONS ARE ON EVERY BOTTLE

GLYCO-HEROIN (SMITH)

For
- Coughs
- Bronchitis
- Phthisis
- Whooping Cough
- Pneumonia
- Asthma

An Absolutely Stable and Uniform Product that has gained world-wide distinction through its dependable therapeutic effects.

DOSAGE:

The adult dose of the preparation is one teaspoonful, repeated every two hours or at longer intervals, according to the requirements of the individual case. For Children of ten or more years, from one-quarter to one-half teaspoonful. For children of three or more years, from five to ten drops.

Confect PARAFFINI AROMAT.

— GALE'S —

An agreeable preparation of "PARAFFINUM" specially purified for internal administration.

It is readily taken by children in doses of from one to two teaspoonfuls, and also by ladies in increased doses according to age, &c.

"GLYCOLACTEIN" (Regd.)

— GALE'S —

An excellent combination of the Glycerophosphates of Lime, Magnesia, and Soda with the chief constituents of Milk.

It is very palatable and does not derange the stomach. It considerably aids digestive processes and tends to increase the appetite and produce a marked improvement in the nutrition of enfeebled and convalescent patients.

LISTERINE

is an efficient, non-toxic antiseptic of known and definite power, prepared in a form convenient for immediate use.

It is a saturated solution of boric acid, reinforced by the antiseptic properties of ozoniferous oils.

It is unirritating, even when applied to the most delicate tissue.

It does not coagulate serous albumen.

It is quite generally accepted as the standard antiseptic preparation for use where a poisonous or corrosive disinfectant can not be safely used.

It is particularly useful in the treatment of abnormal conditions of the mucosa, and admirably suited for a wash, gargle, or douche in catarrhal conditions of the nose and throat.

In proper dilution, it may be freely and continuously used without prejudicial effect, either by injection or spray, in all the natural cavities of the body.

There is no possibility of poisonous effect through the absorption of Listerine.

A pamphlet descriptive of the antiseptic, and indicating its utility in medical, surgical, and dental practice, may be had upon application to the manufacturers, Lambert Pharmacal Co., Locust and Twenty-first Streets, St. Louis, Missouri, U.S.A., or to their British Agents, Messrs. S. Maw, Son and Sons, 7-12, Aldersgate-street, London, Eng., but the best advertisement of Listerine is

NORWOOD SANATORIUM, LTD.,

REMOVED TO

THE MANSION, BECKENHAM PARK, KENT.

UNDER A COMMITTEE OF WELL-KNOWN MEDICAL MEN whose names will be supplied to any Member of the Profession on application to the Resident Medical Superintendent. The object is to apply to the treatment of Alcoholic and Drug Inebriety all available knowledge, and, by accurate observation and record of cases, to extend that knowledge, and place the therapeutics of Inebriety upon a definite scientific basis. The treatment is of such a nature that the restrictions common to Retreats need not be enforced. In many cases a residence of six weeks is sufficient. The Sanatorium consists of a large family mansion, recently redecorated and brought up-to-date in all respects. It is situated in a large and beautifully wooded private park in near proximity to London. All information to be obtained from the Resident Medical Superintendent. Consultations at 13, Welbeck-street, W., every afternoon by appointment.

Telegrams: "NOROTORIUM, BECKENHAM." Resident Medical Superintendent: FRANCIS HARE, M.D. *Telephone:* [illegible] BROMLEY.

INEBRIETY.

For the treatment of Gentlemen under the Act and privately. Established 1883 by an association of prominent medical men and others for the study of inebriety, profits, if any, are expended on the institution. Large secluded grounds on the bank of the river Colne. All kinds of out-door and in-door recreations and pursuits. Terms from 3 guineas weekly.—For particulars, apply to F. S. D. HOGG, M.R.C.S., &c., Resident Medical Superintendent. Telephone: 16 Rickmansworth.

The ALCOHOL and DRUG HABITS, and TRAUMATIC NEURASTHENIA (incidental to war).

GHYLLWOODS,

near COCKERMOUTH, CUMBERLAND. Licensed under the Inebriates Acts. FOR GENTLEMEN ONLY. Privately and under the Acts.

Patients are here treated individually on sound scientific methods, which combine physical and psychical treatment necessary to such cases. The situation of the house in the heart of the English Lake District *is ideal for the purpose to which it is being put.* Private golf course and lake with good trout and coarse fishing, lawn tennis, billiards, workshops, dark room, &c. Good library. References to leading consultants and practitioners. Terms moderate.—Particulars from J. W. ASTLEY COOPER, L.R.C.P., &c., Licensee and Superintendent. Telegrams: "Cooper, Buttermere."

BUNTINGFORD HOUSE RETREAT

BUNTINGFORD, HERTS.

Licensed under the Inebriates Acts, 1879-99.

For Gentlemen suffering from Alcohol and Drug Inebriety; also for Gentlemen Convalescing after Illness. In a most healthy part of the country. 1[illegible] acres of grounds; about 350 feet above sea-level. Electric Light throughout from Private Installation. Golf, Cricket, Tennis, Rifle Range, Croquet, Library, Billiards, Photographic Dark Room, Gardening, Open Air Bath, Carpenter's Shop, Poultry, &c. Quarter mile from Station, G.E.R. Two Resident Physicians.

No Infectious or Consumptive Cases taken. Inebriety Patients are admitted voluntarily only, either privately or under the Inebriate Acts.

Terms from [illegible] guineas. Telephone: P.O. 3 Buntingford. Telegraphic Address: "RESIDENT, BUNTINGFORD."

Alcohol and Drug Inebriety and Neurasthenia.

INVERNITH SANATORIUM, COLINSBURGH, FIFE, SCOTLAND.

(Licensed under the Inebriates Acts.) FOR GENTLEMEN ONLY.

(Under the direction of an Advisory Council of eminent Medical Men.)

NEURASTHENIA is treated on approved principles, and there are Open-air Shelters in the grounds for suitable patients.

INEBRIETY and **NARCOMANIA** are treated on definite medical lines, and the most approved scientific means are employed in the curative treatment. The Resident Medical Superintendents have each patient under their personal care and observation. The curative treatment is much aided by the healthy situation of the Sanatorium and by its isolation from temptation.

The Sanatorium stands 450 feet above the sea, faces south, and looks out over the Firth of Forth. The climate is dry and bracing. All out-door and in-door sports. First-class private golf course. Excellent mixed shooting over 1600 acres, fishing, tennis, gardening, carpentry, &c. Billiard room (two tables), music room, large private library.

References to leading physicians in the chief centres given on application.

For all particulars of Invernith Sanatorium, Ltd., apply to the *Resident Medical Superintendent*, W. H. BRYCE, M.B., C.M.

Telegrams: "Salubrious," Upper Largo. Telephone No 8, Upper Largo. Station—Kilconquhar (N. B. Railway).

MENDIP HILLS SANATORIUM, FOR THE OPEN-AIR TREATMENT.

Old-established, beautifully situated. 300 acres of Sanatorium grounds. Pinewoods and sheltered avenues. Altitude 850 feet. Porous subsoil. Separate châlets, with verandahs, hot-water radiators, and electric light. Special features—breathing and graduated exercises, and continuous inhalation. Individual attention. *Resident Physician*—**C. MUTHU, M.D., M.R.C.S., L.R.C.P.**

Terms 3 guineas weekly. For particulars apply, **SECRETARY, Hillgrove, Wells, Somerset.**

VALE OF CLWYD SANATORIUM.

This Sanatorium (opened 1901) is established for the Treatment of Tuberculosis as carried out by Dr. OTTO WALTHER of Nordrach. It is situated in the midst of a large area of park-land, at a height of 450 feet above the sea-level, on the western slopes of mountains rising to over 1800 feet, which protect it from North and East winds and provide many miles of carefully graduated uphill walks—similar in character and extent to those at Nordrach.

Small rainfall. Porous subsoil. Large amount of sunshine. Electric Lighting and Hot Water Radiators in each room.

The physician himself was a patient at Nordrach.

For particulars apply to GEORGE A. CRACE-CALVERT, M.B., &c., Llanbedr Hall, Ruthin, North Wales.

Salary at the rate of £90 per annum, with board, residence, and laundry, and an honorarium of £10 on completion of six months' service. The hospital is a general hospital for women and children, has 42 beds and special departments for Diseases of Eye, Ear, Nose and Throat, Diseases of Women, and X-Rays.

Applications, with copies of three recent testimonials, to be sent to

N.B.—Ladies are invited to apply. A. ERNEST WILKES,
8th December, 1914. Secretary.

Stoke-upon-Trent Union.—Appointment of ASSISTANT RESIDENT MEDICAL OFFICER.—The Guardians of the Poor of the above-named Union invite applications (male or female) for the appointment of an Assistant Resident Medical Officer for their institution and hospital, situate at London-road, Newcastle, Staffs. The institution has beds for 1289 inmates (present number of inmates 1000), 447 of which are in hospital, maternity, and isolation wards, and 180 in lunacy wards, possesses an up-to-date operating theatre, and is a training school for nurses. Further particulars will be furnished upon application.

The appointment will be subject to the approval of the Local Government Board.

Salary £200 per annum inclusive, with rations, furnished apartments, and washing. No extra fees.

Candidates must be single, duly qualified registered medical practitioners, and the lady or gentleman appointed must devote the whole of their time to the duties of the office.

Applications, stating age, qualifications, and experience, with copies of not more than three recent testimonials, to be sent to the undersigned not later than the 30th day of December, 1914.

T. WOOD, Clerk to the Guardians.
Union Offices, Stoke-on-Trent, 9th December, 1914.

National Hospital for Diseases of the HEART, Westmoreland-street, W. — RESIDENT MEDICAL OFFICER (male or female).—The Committee of Management invites applications for the post of Resident Medical Officer (male or female). The appointment is for a period of six months, but may be renewed for a further period of six months. Salary at the rate of £80 per annum, with board, residence, and washing. Candidates must be fully registered medical practitioners; they are not required to call upon the medical staff, but will be expected to attend the meeting of the Medical Committee.

Applications, stating age, and accompanied by six copies of three recent testimonials, should be addressed to me immediately.

ROBERT G. E. WHITNEY, Secretary.

Edmonton Union (500 beds).— SECOND ASSISTANT MEDICAL OFFICER.—The Guardians of the Edmonton Union require the services of a Second Assistant Medical Officer (male) at their Infirmary, 77, Bridport-road, Upper Edmonton. Commencing salary £160 per annum, with residential allowances.

Applicants must be single men not under twenty-four years of age, and must be fully qualified and registered; a graduate preferred. Previous hospital and anæsthetic experience desirable.

Any further information regarding the appointment can be obtained from Spencer Mort, F.R.C.S., M.D., F.R.S.E.

Applications, on forms which may be obtained from me by sending a stamped addressed foolscap envelope, must be received by me not later than the 5th January, 1915.

White Hart-lane, Tottenham, N. F. SHELTON, Clerk.

City and County of the City of Chester. —ASSISTANT MEDICAL OFFICER OF HEALTH.—Applications are invited for the appointment of Assistant Medical Officer of Health for the City of Chester, at a salary of £300 per annum. The work will include, among other duties, school medical inspection, and the whole time of the officer must be given to the duties of the office.

Candidates shall be between the ages of twenty-five and forty years, and shall possess recognised qualifications in Medicine, Surgery, and Midwifery, and hold a Diploma in Public Health.

Canvassing, either directly or indirectly, will be a disqualification. Applications, accompanied by copies (not returnable) of four testimonials, on forms to be obtained from the undersigned, must be received not later than Monday, the 11th January next.

J. H. DICKSON, Town Clerk.
Town Hall, Chester, 16th December, 1914.

County Borough of Stoke-on-Trent. TUBERCULOSIS SANATORIUM.—Appointment of RESIDENT ASSISTANT MEDICAL OFFICER.—The Town Council invite applications for the position of Resident Assistant Medical Officer at the Stanfield Sanatorium and Assistant at the Tuberculosis Dispensary. Pending the provision of residential accommodation at the Sanatorium he will be required to reside near to the sanatorium, and the salary will be at the rate of £250 per annum inclusive. As soon, however, as residence is provided at the Sanatorium he will be required to reside there, and the salary will then be £200 per annum, with board and residence. He will act under the directions of the Tuberculosis Officer.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, and endorsed, "Resident Assistant Medical Officer," should be delivered to the undersigned not later than 12 noon on Friday, 1st January, 1915.

Canvassing members of the Council will be a disqualification.

E B. SHARPLEY, Town Clerk.
Town Hall, Stoke-on-Trent, Nov. 20th, 1914.

Tunbridge Wells General Hospital.— Wanted, a HOUSE SURGEON (unmarried, male). Candidates must be duly qualified in Medicine and Surgery. Anæsthetic experience essential. May be required to give lectures to the nursing staff.

Salary £100 per annum, with board, residence, &c., in the Hospital. Four weeks' holiday allowed per annum and a Locum provided.

This Hospital is approved by the University of London for the purposes of the M.D. and M.S. Examinations.

This Hospital is a section of the Central Military Hospital at Chatham, and is being largely used for the wounded; extra beds have been provided. At the present juncture, to avoid undue pressure, the cases, both Medical and Surgical, are equally divided between the two Residents, the Casualty work also being shared.

Applications, with certificate of registration and copies of testimonials, to be sent to the undersigned as soon as possible.

J. J. WEBB, Secretary.

North Riding of Yorkshire County COUNCIL.—EDUCATION COMMITTEE.—Temporary ASSISTANT SCHOOL MEDICAL OFFICER.—Applications are invited for the post of Temporary Assistant School Medical Officer.

The applicants, limited to males, must be legally qualified and registered, and should have had experience in diseases of children and diseases of the eye and ear.

The candidate appointed will be required to devote the whole of his time to the service of the Committee, to reside at such place as may be approved by the Committee, and to undertake such duties in connexion with school medical work as the Secretary or School Medical Officer may direct.

The salary will be at the rate of £300 per annum with a fixed allowance in addition to cover all expenses except stationery and postage.

Applications, accompanied by copies of three recent testimonials, to be submitted not later than 31st December, 1914, to the Secretary, Education Department, County Hall, Northallerton.

December 15th, 1914.

Lectureship on Chemical Physiology in EDINBURGH UNIVERSITY. — Applications for the above post may be sent to Professor Sir EDWARD SCHÄFER, University New Buildings, Edinburgh, from whom full particulars may be obtained.

The Lecturer is also an Assistant to the Professor of Physiology. The emoluments amount to £300 per annum.

ANTIKAMNIA TABLETS

IN RHEUMATISM AND NEURALGIA.

In the administration of remedies to relieve **Pain**, the element of exhilaration should be considered, as many produce such delightful sensations as to make them dangerous to use.

Such is not the case with **Antikamnia Tablets.** They are simply pain relievers—not stimulants—not intoxicants. Their use is not followed by depression of the heart.

In cases of **Acute Neuralgia,** tested with a view of determining the analgesic properties of Antikamnia, it has been found to exceed any of its predecessors in rapidity and certainty of the relief given. **Neuralgia, Myalgia, Hemicrania,** and all forms of **Headache, Menstrual Pain,** &c., yield to its influence in a remarkably short time, and in no instance has any evil after-effect developed. Strongly recommended in **Rheumatism.** The adult dose is one or two tablets every one, two, or three hours. To be repeated as indicated. All genuine Tablets bear the AK monogram.

TO TREAT A COUGH. Antikamnia & Codeine Tablets are most useful. It matters not whether it be a deep-seated cough, tickling cough, hacking cough, nervous cough, or whatever its character, it can be brought under prompt control by these Tablets. To administer Antikamnia & Codeine Tablets most satisfactorily for coughs advise patients to allow one or two Tablets to dissolve slowly upon the tongue and swallow the saliva. For night coughs take one on retiring.

ANALGESIC. ANTIPYRETIC. ANODYNE.

ANTIKAMNIA TABLETS, 5 gr. ANTIKAMNIA & CODEINE TABLETS.
Supplied in 1-oz. packages to the Medical Profession.

THE ANTIKAMNIA CHEMICAL COMPANY, 46, Holborn Viaduct, London.

The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.

DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

In **Hospital** and **Private Practice** during **Epidemics** and **in their own persons** when ill, **Physicians** have demonstrated the **Value** of **Valentine's Meat-Juice** in **Sustaining** and **Strengthening** the weakened **Vital Forces.**

Pneumonia and Influenza.

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients and also personally after having been ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

Edward C. Seufert, M. D., *Professor Histology and Pathology, Illinois Medical College, Chicago:* "I have always been a user of the valuable preparation, VALENTINE'S MEAT-JUICE. The best results that I have obtained from it have been in Typhoid Fever and Broncho-Pneumonia of children. I believe that the samples sent helped to save the child of one of my students at the College."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
D 175 **RICHMOND, VIRGINIA, U. S. A.**

PRINTED and PUBLISHED by the PROPRIETORS, WAKLEY AND SON (1912), LTD., at No. 423, Strand, and Nos. 1 and 2, Bedford-street, adjoining in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London, and sold by all Booksellers and Newsvendors in Great Britain and Ireland and the Colonies.—Saturday, Dec. 26th, 1914.

CLIN LABORATORIES — PARIS

"A revolution in the art of Urine testing."—MEDICAL PRESS & CIRCULAR.

ENDOLYTIC TUBES.

Hermetically sealed Capillary Tubes, by means of which a specimen of **Urine** can, in a few moments, be accurately **tested at the Bedside,** for Albumin and Albumose; Glucose; Acetone, and Diacetic Acid.

"An ingenious and delicate means of testing Urine."—THE LANCET.

"The reactions were obtained most satisfactorily and with great ease."—THE BRITISH MEDICAL JOURNAL.

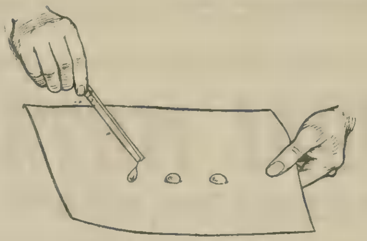

Fig. 1.

A few drops of urine are transferred to a quarter-sheet of note paper by means of a folded strip of paper.

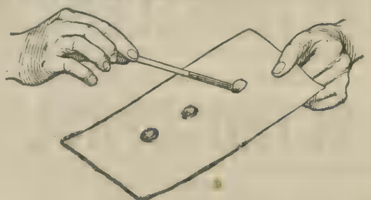

Fig. 2.

The end of the Endolytic Tube is allowed to touch one of the drops of urine, when the latter will be absorbed into the reagent by capillary attraction.

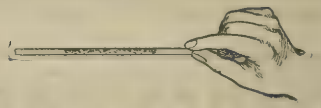

Fig. 3.

The Salicyl-Sulphonic Acid reagent will indicate the merest trace of Albumin. The negative results are always **absolute,** and the positive results free from fallacies. A precipitate with Salicyl-Sulphonic Acid is either Albumin (*kidney condition*) or Albumose (*not a kidney condition*). To distinguish, heat the Endolytic Tube as described under the next test. Permanence of the precipitate indicates Albumin, while its disappearance on heating indicates Albumose.

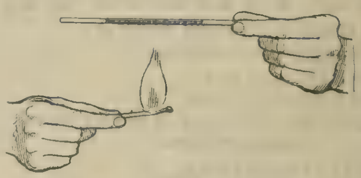

Fig. 4.

After a drop of urine has been absorbed in the Fehling Tube, the reaction may be completed by heating with a wax vesta, or (preferably) by a little boiling water.

ENDOLYTIC TUBES for each of the above tests are supplied by the leading Surgical Instrument Dealers and Chemists, in boxes of [illegible] at 2/- each. Cases containing four boxes (100 Tubes) all one kind or assorted 7/6, including nickel-plated pocket case.
